7 Indices and tables	113
Python Module Index	115
Index	117

TFA is a method that builds on FBA to improve its solution space. Specifically, it includes thermodynamics and explicit formulation of Gibbs energies and metabolite concentrations, which enables straightforward integration of metabolite concentration measurements.

If you use our work, please cite us¹ !

¹ Salvy, P., Fengos, G., Ataman, M., Pathier, T., Soh, K. C., & Hatzimanikatis, V. (2018). pyTFA and matTFA: a Python package and a Matlab toolbox for Thermodynamics-based Flux Analysis. *Bioinformatics*, 35(1), 167-169.

QUICK START

Three tutorial files detail thoroughly normal usages of the pytfa package. They can be found at:

```
pytfa
├── tutorials
│   ├── figure_paper.py
│   ├── tutorial_basics.py
│   └── tutorial_sampling.py
```

figure_paper.py details how to get the figure from our paper¹, a simple use case for TFA on a reduced *Escherichia coli*. We show that adding thermodynamics constraints and simple concentration data allow to substantially reduce the flux space.

tutorial_basics.py shows a more realistic case with two models (reduced or full genome-scale) of *Escherichia coli*. It also cycles through several solvers (if more are installed), to show how simple it is to change your solver (thanks to [optlang](#)).

tutorial_sampling.py shows how to sample a variable, for example thermodynamic displacement, and generate plots to visualize the results.

If you plan to run the tutorials with full genome-scale models, we recommend you to get a commercial solver, as it has been seen that GLPK's lack of parallelism significantly increases solving time

The next sections give more details on how the thermodynamic model is structured, and how data is managed.

Cheers,

The py.TFA team

¹ Salvy, P., Fengos, G., Ataman, M., Pathier, T., Soh, K. C., & Hatzimanikatis, V. (2018). pyTFA and matTFA: a Python package and a Matlab toolbox for Thermodynamics-based Flux Analysis. *Bioinformatics*, 35(1), 167-169.

PYTFA MODELS

pyTFA models are based on COBRApy models, with additional values.

2.1 Compartment data

This is the `compartments` attribute of the model. It is a *dict* where each key is the symbol of a compartment, and the value is another *dict* with the following keys :

<code>c_min</code>	<i>float</i> The minimum concentration for each metabolite in the compartment, in mol.L-1
<code>c_max</code>	<i>float</i> The maximum concentration for each metabolite in the compartment, in mol.L-1
<code>ionicStr</code>	<i>float</i> The ionic strength of the compartment (mV)
<code>membranePot</code>	<i>dict</i> A dictionary representing the membrane potential between this compartment (which is the source compartment) and the others. Each key is the symbol of another compartment (which is the destination compartment), and the value is the potential (in mV) from the source to the destination.
<code>name</code>	<i>string</i> The name of the compartment
<code>pH</code>	<i>float</i> The pH in the compartment
<code>symbol</code>	<i>string</i> The symbol of the compartment (which is the key of this dictionary)

Here is an example:

```
cobra_model.compartments['c'] = {
    'c_max': 0.01,
    'c_min': 9.9999999999999995e-08,
    'ionicStr': 0.25,
    'membranePot': {
        'c': 0,
        'e': 60,
        'g': 0,
        'm': -180,
        'n': 0,
        'p': 0,
        'r': 0,
        't': 0,
        'v': 0,
        'x': 0
    },
}
```

(continues on next page)

(continued from previous page)

```
'name': 'Cytosol',
'pH': 7.0,
'symbol': 'c'
}
```

2.2 Metabolites

Each metabolite must be annotated with its SeedID, which will be used to get the thermodynamic values from the *Thermodynamic Databases*. In order to do this, use the `annotation` attribute of each metabolite. Here is an example:

```
cobra_model.metabolites[0].annotation = {
  'SeedID': 'cpd00018'
}
```

pyTFA will also define a `thermo` attribute for each metabolite, which is a `pytfa.thermo.MetaboliteThermo`.

2.3 Reactions

pyTFA will define a `thermo` attribute for each reaction. It is a `dict` with the following attributes:

computed	<code>bool</code> Whether the thermodynamic values were computed or not.
deltaGR	<code>float</code> Sum of the non-concentration terms for the reaction. Used as the right-hand side value of a constraint. If the thermodynamic values were not computed, this is 10^{*7} .
deltaGRerr	<code>float</code> Error on deltaGR If the thermodynamic values were not computed, this is 10^{*7} .
deltaGrxn	<code>float</code> Sum of the deltaGF of all the metabolites in the reaction. Not defined if computed is False !
isTrans	<code>bool</code> Whether the reaction is a transport reaction or not

Here are some examples:

```
cobra_model.reactions[0].thermo = {
  'computed': False,
  'deltaGR': 10000000,
  'deltaGRerr': 10000000,
  'isTrans': False
}

cobra_model.reactions[99].thermo = {
  'computed': True,
  'deltaGR': 1.161097833014658,
  'deltaGRerr': 2,
  'deltaGrxn': 0,
}
```

(continues on next page)

(continued from previous page)

```
'isTrans': True,  
}
```

THERMODYNAMIC DATABASES

3.1 Converting a Matlab thermodynamic database

If you have a Matlab thermodynamic database, you can easily convert it to a Python database thanks to the script `thermoDBconverter.py`:

```
python thermoDBconverter.py database.mat converted_database.thermodb
```

3.2 Loading a thermodynamic database

Thermodynamic databases are compressed through `zlib` and binary-encoded with `pickle`. In order to load them, you need first to uncompress them with `zlib.decompress` then load the result into memory with `pickle.loads`:

```
import pickle
import zlib
with open('thermoDatabases/DB_AlbertyUpdate.thermodb', 'rb') as file:
    ReactionDB = pickle.loads(zlib.decompress(file.read()))
```

Warning: Since the file is compressed, you **MUST** load it as a binary file by calling `open` with the `b` flag, otherwise Python will try to decode it as unicode and raise an exception !

3.3 Structure of a thermodynamic database

A thermodynamic database is a *dict* with the following fields:

- `name` : *string* The name of the database
- `units` : *string* The unit of the energies in the database. Can be kcal/mol or kJ/mol.
- `metabolites` : *dict* A dictionary containing the metabolites' thermodynamic data. See *Metabolites* for more information.
- `cues` : *dict* A dictionary containing the cues' thermodynamic data. See *Cues* for more information.

3.3.1 Metabolites

This is a dictionary storing various thermodynamic data about metabolites. It is stored as a `dict` where each key is a SeedID. The values are others `dict` with the following keys.

<code>id</code>	<code>string</code> SeedID of the metabolite
<code>charge_std</code>	<code>float</code> Charge of the metabolite (mV) in standard conditions
<code>delt-aGf_std</code>	<code>float</code> Transformed Gibbs energy of formation of the metabolite, in standard conditions.
<code>delt-aGf_err</code>	<code>float</code> Error on the transformed Gibbs energy of formation of the metabolite, in standard conditions
<code>mass_std</code>	<code>float</code> Mass of the metabolite (g.mol-1)
<code>nH_std</code>	<code>int</code> Number of protons of the metabolite, in standard conditions
<code>error</code>	<code>string</code> Error on the metabolite's thermodynamic data. Thermodynamic values will be computed only if this equals to 'Nil'.
<code>formula</code>	<code>string</code> Formula of the metabolite.
<code>nH_std</code>	<code>int</code> Number of protons in the metabolite's formula
<code>name</code>	<code>string</code> Name of the metabolite
<code>other_names</code>	<code>list (string)</code> Other names of the metabolite
<code>pKa</code>	<code>list (float)</code> pKas of the metabolite
<code>struct_cues</code>	<code>dict (int)</code> cues of the metabolite The keys of the array are the names of the cues, and the values the number of cues of this type that are part of the structure.

Here is an example:

```
ReactionDB['metabolites']['cpd00001'] = {
  'charge_std': 0,
  'deltaGf_err': 0.5,
  'deltaGf_std': -56.686999999999998,
  'error': 'Nil',
  'formula': 'H2O',
  'id': 'cpd00001',
  'mass_std': 18.0,
  'nH_std': 2,
  'name': 'H2O',
  'other_names': ['H2O', 'Water', 'HO-', 'OH-', 'h2o'],
  'pKa': [15.7],
  'struct_cues': {'H2O': 1}
}
```

3.3.2 Cues

This is a dictionary storing various thermodynamic data about cues. It is stored as a `dict` where each key is the cue ID, as referenced in the `struct_cues` attribute of *Metabolites*. The values are others `dict` with the following keys.

<code>id</code>	<code>string</code> ID of the cue
<code>charge</code>	<code>float</code> The charge (mV) of the cue in standard conditions
<code>datfile</code>	<code>string</code> The dat file from which the data was imported. <i>Optional</i>
<code>energy</code>	<code>float</code> Transformed Gibbs energy of formation of the cue, in standard conditions.
<code>error</code>	<code>float</code> The error on the transformed Gibbs energy of formation of the cue, in standard conditions.
<code>formula</code>	<code>string</code> Formula of the cue
<code>names</code>	<code>list (string)</code> Other names of the cue
<code>small</code>	<code>bool</code> Whether this is a small cue or not

Here is an example:

```
ReactionDB['cues']['H2O'] = {
  'charge': 0,
  'datfile': 'H2O.gds',
  'energy': -56.686999999999998,
  'error': 0.5,
  'formula': 'H2O',
  'id': 'H2O',
  'names': ['H2O', 'OH-', 'HO-'],
  'small': True
}
```

SOLVER SETUP

This document is written assuming a Docker container installation. However, you can easily adapt the content to other types of Linux-based installations.

4.1 GPLK

GLPK should be directly available from the requirements.

4.2 CPLEX

You will need to first install CPLEX on a Linux machine.

Place in *etfl/docker/solvers/* the folder *ibm* that is installed by CPLEX (usually in */opt*). You actually only need the following substructure (makes the container lighter):

4.3 Gurobi

Place in *etfl/docker/solvers/* the tarball you downloaded from the website, and modify accordingly the files:

```
../utils/install_gurobi.sh
../utils/activate_gurobi.sh
```

Make sure you change the paths and filenames to reflect the actual version of Gurobi you are running.

Gurobi needs a floating license for Docker instances, (see http://www.gurobi.com/documentation/7.5/quickstart_windows/setting_up_and_using_a_flo.html#subsection:tokenserver) Once your system administrator set it up, you will need to add your gurobi license server to *../utils/gurobi.lic.template*, and rename it to *gurobi.lic*

INTEGRATING METABOLOMICS

In this short example we will go through a simple case of integration of absolute metabolite concentrations.

Let us imagine we got absolute concentration values for cytosolic ATP:

$$5 \cdot 10^{-3} \text{ mol.L}^{-1} \leq [X] \leq 3 \cdot 10^{-2} \text{ mol.L}^{-1}$$

Then you can tell the model that your (log) concentration is limited in range:

```
from math import log  
  
mymodel.log_concentration.atp_c.variable.lb = log(5e-3)  
mymodel.log_concentration.atp_c.variable.ub = log(3e-2)
```

This will constrain the dG according to your concentration measurements for cytosolic ATP. As a reminder, the dG (not the dGo) takes activity (here, concentrations) into account for its calculation. You can find a more detailed explanation in those papers:

- Henry, Christopher S., Linda J. Broadbelt, and Vassily Hatzimanikatis. “Thermodynamics-based metabolic flux analysis.” *Biophysical journal* 92.5 (2007): 1792-1805.
- Soh, Keng Cher, Ljubisa Miskovic, and Vassily Hatzimanikatis. “From network models to network responses: integration of thermodynamic and kinetic properties of yeast genome-scale metabolic networks.” *FEMS yeast research* 12.2 (2012): 129-143.

API REFERENCE

This page contains auto-generated API reference documentation¹.

6.1 `pytfa`

Thermodynamic analysis for Flux-Based Analysis

6.1.1 Subpackages

`pytfa.analysis`

Submodules

`pytfa.analysis.chebyshev`

Variability analysis

Module Contents

Classes

`ChebyshevRadius`

Variable representing a Chebyshev radius

¹ Created with `sphinx-autoapi`

Functions

<code>is_inequality(constraint)</code>	
<code>chebyshev_center(model, variables, inplace=False, big_m=BIGM, include=list(), exclude=list())</code>	Computes the chebyshev center of a problem with respect to given variables,
<code>chebyshev_transform(model, vars, include_list=list(), exclude_list=list(), radius_id='radius', scaling_factor=1, big_m=BIGM)</code>	Adds a Chebyshev radius variable and edits accordingly the selected
<code>get_cons_var_classes(model, elements, type)</code>	
<code>get_variables(model, variables)</code>	

Attributes

<code>BIGM</code>

`pytfa.BIGM = 1000`

`class pytfa.ChebyshevRadius(model, id_, **kwargs)`

Bases: `pytfa.optim.variables.ModelVariable`

Variable representing a Chebyshev radius

`prefix = CR_`

`pytfa.is_inequality(constraint)`

`pytfa.chebyshev_center(model, variables, inplace=False, big_m=BIGM, include=list(), exclude=list())`

Computes the chebyshev center of a problem with respect to given variables, including 'include' constraints and excluding 'exclude' constraints. *Warning: Only works with pyTFA variables so far*

Parameters

- `model` –
- `variables` –
- `inplace` –
- `big_m` –

Returns

`pytfa.chebyshev_transform(model, vars, include_list=list(), exclude_list=list(), radius_id='radius', scaling_factor=1, big_m=BIGM)`

Adds a Chebyshev radius variable and edits accordingly the selected constraints

Parameters

- `model` –
- `vars` – variables with respect to which to perform the Chebyshev centering. If none is supplied, all of the variables in the equation will be considered

- `include_list` –
- `exclude_list` –
- `radius_id` –
- `big_m` –

Returns

`pytfa.get_cons_var_classes(model, elements, type)`

`pytfa.get_variables(model, variables)`

`pytfa.analysis.manipulation`

Module Contents

Functions

<code>apply_reaction_variability</code> (<i>tmodel</i> , <i>va</i> , <i>inplace=True</i>)	in-	Applies the VA results as bounds for the reactions of a cobra_model
<code>apply_generic_variability</code> (<i>tmodel</i> , <i>va</i> , <i>inplace=True</i>)	in-	Reactions a dealt with cobra, but the other variables added use pytfa's
<code>apply_directionality</code> (<i>tmodel</i> , <i>solution</i> , <i>inplace=True</i>)	in-	Takes a flux solution and transfers its reaction directionality as

`pytfa.analysis.manipulation.apply_reaction_variability(tmodel, va, inplace=True)`

Applies the VA results as bounds for the reactions of a cobra_model :param inplace: :param tmodel: :param va: :return:

`pytfa.analysis.manipulation.apply_generic_variability(tmodel, va, inplace=True)`

Reactions a dealt with cobra, but the other variables added use pytfa's interface: the class GenericVariable. We use a different method to apply variability directly in the solver

Parameters

- `tmodel` –
- `va` –
- `inplace` –

Returns

`pytfa.analysis.manipulation.apply_directionality(tmodel, solution, inplace=True)`

Takes a flux solution and transfers its reaction directionality as constraints for the cobra_model

Parameters

- `inplace` –
- `tmodel` –
- `solution` –

Returns

pytfa.analysis.sampling

Sampling wrappers for pytfa models

Module Contents

Classes

<code>GeneralizedHRSampler</code>	The abstract base class for hit-and-run samplers.
<code>GeneralizedACHRSampler</code>	The abstract base class for hit-and-run samplers.
<code>GeneralizedOptGPSampler</code>	The abstract base class for hit-and-run samplers.

Functions

<code>sample(model, n, method='optgp', thinning=100, processes=1, seed=None)</code>	Sample valid flux distributions from a thermo cobra_model.
---	--

class `pytfa.GeneralizedHRSampler`(*model, thinning, nproj=None, seed=None*)

Bases: `cobra.sampling.HRSampler`

The abstract base class for hit-and-run samplers.

New samplers should derive from this class where possible to provide a uniform interface.

model

[`cobra.Model`] The cobra model from which to generate samples.

thinning

[`int`] The thinning factor of the generated sampling chain. A thinning of 10 means samples are returned every 10 steps.

nproj

[`int > 0`, optional] How often to reproject the sampling point into the feasibility space. Avoids numerical issues at the cost of lower sampling. If you observe many equality constraint violations with `sampler.validate` you should lower this number (default `None`).

seed

[`int > 0`, optional] Sets the random number seed. Initialized to the current time stamp if `None` (default `None`).

feasibility_tol: float

The tolerance used for checking equalities feasibility.

bounds_tol: float

The tolerance used for checking bounds feasibility.

n_samples

[`int`] The total number of samples that have been generated by this sampler instance.

retries

[`int`] The overall of sampling retries the sampler has observed. Larger values indicate numerical instabilities.

problem

[`Problem`] A `NamedTuple` whose attributes define the entire sampling problem in matrix form.

warmup

[numpy.matrix] A numpy matrix with as many columns as reactions in the model and more than 3 rows containing a warmup sample in each row. None if no warmup points have been generated yet.

fwd_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective forward variable.

rev_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective reverse variable.

generate_fva_warmup(*self*)

Generate the warmup points for the sampler.

Generates warmup points by setting each flux as the sole objective and minimizing/maximizing it. Also caches the projection of the warmup points into the nullspace for non-homogeneous problems (only if necessary).

class pytfa.**GeneralizedACHRSampler**(*model*, *thinning*=100, *seed*=None)

Bases: *GeneralizedHRSampler*, cobra.sampling.ACHRSampler

The abstract base class for hit-and-run samplers.

New samplers should derive from this class where possible to provide a uniform interface.

model

[cobra.Model] The cobra model from which to generate samples.

thinning

[int] The thinning factor of the generated sampling chain. A thinning of 10 means samples are returned every 10 steps.

nproj

[int > 0, optional] How often to reproject the sampling point into the feasibility space. Avoids numerical issues at the cost of lower sampling. If you observe many equality constraint violations with *sampler.validate* you should lower this number (default None).

seed

[int > 0, optional] Sets the random number seed. Initialized to the current time stamp if None (default None).

feasibility_tol: float

The tolerance used for checking equalities feasibility.

bounds_tol: float

The tolerance used for checking bounds feasibility.

n_samples

[int] The total number of samples that have been generated by this sampler instance.

retries

[int] The overall of sampling retries the sampler has observed. Larger values indicate numerical instabilities.

problem

[Problem] A NamedTuple whose attributes define the entire sampling problem in matrix form.

warmup

[numpy.matrix] A numpy matrix with as many columns as reactions in the model and more than 3 rows containing a warmup sample in each row. None if no warmup points have been generated yet.

fwd_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective forward variable.

rev_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective reverse variable.

class pytfa.**GeneralizedOptGPSampler**(*model, processes, thinning=100, seed=None*)

Bases: *GeneralizedHRSampler*, cobra.sampling.OptGPSampler

The abstract base class for hit-and-run samplers.

New samplers should derive from this class where possible to provide a uniform interface.

model

[cobra.Model] The cobra model from which to generate samples.

thinning

[int] The thinning factor of the generated sampling chain. A thinning of 10 means samples are returned every 10 steps.

nproj

[int > 0, optional] How often to reproject the sampling point into the feasibility space. Avoids numerical issues at the cost of lower sampling. If you observe many equality constraint violations with *sampler.validate* you should lower this number (default None).

seed

[int > 0, optional] Sets the random number seed. Initialized to the current time stamp if None (default None).

feasibility_tol: float

The tolerance used for checking equalities feasibility.

bounds_tol: float

The tolerance used for checking bounds feasibility.

n_samples

[int] The total number of samples that have been generated by this sampler instance.

retries

[int] The overall of sampling retries the sampler has observed. Larger values indicate numerical instabilities.

problem

[Problem] A NamedTuple whose attributes define the entire sampling problem in matrix form.

warmup

[numpy.matrix] A numpy matrix with as many columns as reactions in the model and more than 3 rows containing a warmup sample in each row. None if no warmup points have been generated yet.

fwd_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective forward variable.

rev_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective reverse variable.

`pytfa.sample(model, n, method='optgp', thinning=100, processes=1, seed=None)`

Sample valid flux distributions from a thermo cobra_model.

Function adapted from cobra.flux_analysis.sample to display all solver variables

Documentation adapted from cobra.flux_analysis.sample

1. **'optgp' (default) which uses the OptGPSampler that supports parallel analysis**¹. Requires large numbers of samples to be performant (n < 1000). For smaller samples 'achr' might be better suited.

or

2. **'achr' which uses artificial centering hit-and-run**. This is a single process method with good convergence².

model

[pytfa.core.ThermoModel] The cobra_model from which to sample variables.

n

[int] The number of samples to obtain. When using 'optgp' this must be a multiple of *processes*, otherwise a larger number of samples will be returned.

method

[str, optional] The analysis algorithm to use.

thinning

[int, optional] The thinning factor of the generated analysis chain. A thinning of 10 means samples are returned every 10 steps. Defaults to 100 which in benchmarks gives approximately uncorrelated samples. If set to one will return all iterates.

processes

[int, optional] Only used for 'optgp'. The number of processes used to generate samples.

seed

[positive integer, optional] The random number seed to be used. Initialized to current time stamp if None.

pandas.DataFrame

The generated flux samples. Each row corresponds to a sample of the fluxes and the columns are the reactions.

The samplers have a correction method to ensure equality feasibility for long-running chains, however this will only work for homogeneous models, meaning models with no non-zero fixed variables or constraints (right-hand side of the equalities are zero).

pytfa.analysis.variability

Variability analysis

Module Contents

Functions

<code>find_bidirectional_reactions(va, tolerance=1e-08)</code>	Returns the ids of reactions that can both carry net flux in the forward or
<code>find_directionality_profiles(tmodel, bidirectional, max_iter=10000.0, solver='optlang-glpk')</code>	Takes a ThermoModel and performs enumeration of the directionality profiles
<code>_bool2str(bool_list)</code>	turns a list of booleans into a string
<code>_variability_analysis_element(tmodel, var, sense)</code>	
<code>variability_analysis(tmodel, kind='reactions', proc_num=BEST_THREAD_RATIO)</code>	Performs variability analysis, given a variable type
<code>parallel_variability_analysis(tmodel, kind='reactions', proc_num=BEST_THREAD_RATIO)</code>	WIP.
<code>calculate_dissipation(tmodel, solution=None)</code>	

Attributes

<code>CPU_COUNT</code>
<code>BEST_THREAD_RATIO</code>

`pytfa.CPU_COUNT`

`pytfa.BEST_THREAD_RATIO`

`pytfa.find_bidirectional_reactions(va, tolerance=1e-08)`

Returns the ids of reactions that can both carry net flux in the forward or backward direction.

Parameters

va –

A variability analysis, pandas Dataframe like so:

```

maximum minimum
6PGLter -8.330667e-04 -8.330667e-04 ABUTt2r 0.000000e+00 0.000000e+00 ACALDt
0.000000e+00 0.000000e+00
    
```

Returns

`pytfa.find_directionality_profiles(tmodel, bidirectional, max_iter=10000.0, solver='optlang-glpk')`

Takes a ThermoModel and performs enumeration of the directionality profiles

Parameters

- **tmodel** –
- **max_iter** –

Returns

`pytfa._bool2str(bool_list)`

turns a list of booleans into a string

Parameters

bool_list – ex: `[False True False False True]`

Returns

`'01001'`

`pytfa._variability_analysis_element(tmodel, var, sense)`

`pytfa.variability_analysis(tmodel, kind='reactions', proc_num=BEST_THREAD_RATIO)`

Performs variability analysis, given a variable type

Parameters

- **tmodel** –
- **kind** –
- **proc_num** –

Returns

`pytfa.parallel_variability_analysis(tmodel, kind='reactions', proc_num=BEST_THREAD_RATIO)`

WIP.

Parameters

- **tmodel** –
- **kind** –
- **proc_num** –

Returns

`pytfa.calculate_dissipation(tmodel, solution=None)`

Package Contents

Classes

<i>GeneralizedHRSampler</i>	The abstract base class for hit-and-run samplers.
<i>GeneralizedACHRSampler</i>	The abstract base class for hit-and-run samplers.
<i>GeneralizedOptGPSampler</i>	The abstract base class for hit-and-run samplers.
<i>DeltaG</i>	Class to represent a DeltaG
<i>ForbiddenProfile</i>	Class to represent a forbidden net flux directionality profile
<i>ForwardUseVariable</i>	Class to represent a forward use variable, a type of binary variable used to

Functions

<code>sample(model, n, method='optgp', thinning=100, processes=1, seed=None)</code>	Sample valid flux distributions from a thermo cobra_model.
<code>get_direction_use_variables(tmodel, solution)</code>	Returns the active use variables in a solution. Use Variables are binary
<code>get_bistream_logger(name)</code>	Sets up a logger that outputs INFO+ messages on stdout and DEBUG+ messages
<code>find_bidirectional_reactions(va, tolerance=1e-08)</code>	Returns the ids of reactions that can both carry net flux in the forward or
<code>find_directionality_profiles(tmodel, bidirectional, max_iter=10000.0, solver='optlang-glpk')</code>	Takes a ThermoModel and performs enumeration of the directionality profiles
<code>_bool2str(bool_list)</code>	turns a list of booleans into a string
<code>_variability_analysis_element(tmodel, var, sense)</code>	
<code>variability_analysis(tmodel, kind='reactions', proc_num=BEST_THREAD_RATIO)</code>	Performs variability analysis, given a variable type
<code>parallel_variability_analysis(tmodel, kind='reactions', proc_num=BEST_THREAD_RATIO)</code>	WIP.
<code>calculate_dissipation(tmodel, solution=None)</code>	
<code>apply_reaction_variability(tmodel, va, in-place=True)</code>	Applies the VA results as bounds for the reactions of a cobra_model
<code>apply_generic_variability(tmodel, va, in-place=True)</code>	Reactions a dealt with cobra, but the other variables added use pytfa's
<code>apply_directionality(tmodel, solution, in-place=True)</code>	Takes a flux solution and transfers its reaction directionality as

Attributes

`CPU_COUNT`

`BEST_THREAD_RATIO`

class `pytfa.analysis.GeneralizedHRSampler(model, thinning, nproj=None, seed=None)`

Bases: `cobra.sampling.HRSampler`

The abstract base class for hit-and-run samplers.

New samplers should derive from this class where possible to provide a uniform interface.

model

[`cobra.Model`] The cobra model from which to generate samples.

thinning

[int] The thinning factor of the generated sampling chain. A thinning of 10 means samples are returned every 10 steps.

nproj

[int > 0, optional] How often to reproject the sampling point into the feasibility space. Avoids numerical issues at the cost of lower sampling. If you observe many equality constraint violations with `sampler.validate` you should lower this number (default None).

seed

[int > 0, optional] Sets the random number seed. Initialized to the current time stamp if None (default None).

feasibility_tol: float

The tolerance used for checking equalities feasibility.

bounds_tol: float

The tolerance used for checking bounds feasibility.

n_samples

[int] The total number of samples that have been generated by this sampler instance.

retries

[int] The overall of sampling retries the sampler has observed. Larger values indicate numerical instabilities.

problem

[Problem] A NamedTuple whose attributes define the entire sampling problem in matrix form.

warmup

[numpy.matrix] A numpy matrix with as many columns as reactions in the model and more than 3 rows containing a warmup sample in each row. None if no warmup points have been generated yet.

fwd_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective forward variable.

rev_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective reverse variable.

generate_fva_warmup(*self*)

Generate the warmup points for the sampler.

Generates warmup points by setting each flux as the sole objective and minimizing/maximizing it. Also caches the projection of the warmup points into the nullspace for non-homogeneous problems (only if necessary).

class pytfa.analysis.**GeneralizedACHRSampler**(*model*, *thinning=100*, *seed=None*)

Bases: *GeneralizedHRSampler*, cobra.sampling.ACHRSampler

The abstract base class for hit-and-run samplers.

New samplers should derive from this class where possible to provide a uniform interface.

model

[cobra.Model] The cobra model from which to generate samples.

thinning

[int] The thinning factor of the generated sampling chain. A thinning of 10 means samples are returned every 10 steps.

nproj

[int > 0, optional] How often to reproject the sampling point into the feasibility space. Avoids numerical issues at the cost of lower sampling. If you observe many equality constraint violations with *sampler.validate* you should lower this number (default None).

seed

[int > 0, optional] Sets the random number seed. Initialized to the current time stamp if None (default None).

feasibility_tol: float

The tolerance used for checking equalities feasibility.

bounds_tol: float

The tolerance used for checking bounds feasibility.

n_samples

[int] The total number of samples that have been generated by this sampler instance.

retries

[int] The overall of sampling retries the sampler has observed. Larger values indicate numerical instabilities.

problem

[Problem] A NamedTuple whose attributes define the entire sampling problem in matrix form.

warmup

[numpy.matrix] A numpy matrix with as many columns as reactions in the model and more than 3 rows containing a warmup sample in each row. None if no warmup points have been generated yet.

fwd_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective forward variable.

rev_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective reverse variable.

class `pytfa.analysis.GeneralizedOptGPSampler`(*model, processes, thinning=100, seed=None*)

Bases: `GeneralizedHRSampler`, `cobra.sampling.OptGPSampler`

The abstract base class for hit-and-run samplers.

New samplers should derive from this class where possible to provide a uniform interface.

model

[cobra.Model] The cobra model from which to generate samples.

thinning

[int] The thinning factor of the generated sampling chain. A thinning of 10 means samples are returned every 10 steps.

nproj

[int > 0, optional] How often to reproject the sampling point into the feasibility space. Avoids numerical issues at the cost of lower sampling. If you observe many equality constraint violations with `sampler.validate` you should lower this number (default None).

seed

[int > 0, optional] Sets the random number seed. Initialized to the current time stamp if None (default None).

feasibility_tol: float

The tolerance used for checking equalities feasibility.

bounds_tol: float

The tolerance used for checking bounds feasibility.

n_samples

[int] The total number of samples that have been generated by this sampler instance.

retries

[int] The overall of sampling retries the sampler has observed. Larger values indicate numerical instabilities.

problem

[Problem] A NamedTuple whose attributes define the entire sampling problem in matrix form.

warmup

[numpy.matrix] A numpy matrix with as many columns as reactions in the model and more than 3 rows containing a warmup sample in each row. None if no warmup points have been generated yet.

fwd_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective forward variable.

rev_idx

[numpy.array] A numpy array having one entry for each reaction in the model, containing the index of the respective reverse variable.

`pytfa.analysis.sample(model, n, method='optgp', thinning=100, processes=1, seed=None)`

Sample valid flux distributions from a thermo cobra_model.

Function adapted from cobra.flux_analysis.sample to display all solver variables

Documentation adapted from cobra.flux_analysis.sample

1. **'optgp' (default) which uses the OptGPSampler that supports parallel analysis**¹. Requires large numbers of samples to be performant (n < 1000). For smaller samples 'achr' might be better suited.

or

2. 'achr' which uses artificial centering hit-and-run. This is a single process method with good convergence².

model

[pytfa.core.ThermoModel] The cobra_model from which to sample variables.

n

[int] The number of samples to obtain. When using 'optgp' this must be a multiple of *processes*, otherwise a larger number of samples will be returned.

method

[str, optional] The analysis algorithm to use.

thinning

[int, optional] The thinning factor of the generated analysis chain. A thinning of 10 means samples are returned every 10 steps. Defaults to 100 which in benchmarks gives approximately uncorrelated samples. If set to one will return all iterates.

processes

[int, optional] Only used for 'optgp'. The number of processes used to generate samples.

seed

[positive integer, optional] The random number seed to be used. Initialized to current time stamp if None.

pandas.DataFrame

The generated flux samples. Each row corresponds to a sample of the fluxes and the columns are the reactions.

¹ Megchelenbrink W, Huynen M, Marchiori E (2014) optGpSampler: An Improved Tool for Uniformly Sampling the Solution-Space of Genome-Scale Metabolic Networks. PLoS ONE 9(2): e86587.

² Direction Choice for Accelerated Convergence in Hit-and-Run Sampling David E. Kaufman Robert L. Smith Operations Research 199846:1 , 84-95

The samplers have a correction method to ensure equality feasibility for long-running chains, however this will only work for homogeneous models, meaning models with no non-zero fixed variables or constraints (right-hand side of the equalities are zero).

class `pytfa.analysis.DeltaG`(*reaction*, ***kwargs*)

Bases: `ReactionVariable`

Class to represent a DeltaG

prefix = `DG_`

class `pytfa.analysis.ForbiddenProfile`(*model*, *expr*, *id_*, ***kwargs*)

Bases: `GenericConstraint`

Class to represent a forbidden net flux directionality profile Looks like: $FU_{rxn_1} + BU_{rxn_2} + \dots + FU_{rxn_n} \leq n-1$

prefix = `FP_`

`pytfa.analysis.get_direction_use_variables`(*tmodel*, *solution*)

Returns the active use variables in a solution. Use Variables are binary variables that control the directionality of the reaction The difference with `get_active_use_variables` is that variables with both UseVariables at 0 will return as going forwards. This is to ensure that the output size of the function is equal to the number of FDPs

ex: `FU_ACALDt BU_PFK`

Parameters

- **tmodel** (*pytfa.core.ThermoModel*) –
- **solution** –

Returns

class `pytfa.analysis.ForwardUseVariable`(*reaction*, ***kwargs*)

Bases: `ReactionVariable`, `BinaryVariable`

Class to represent a forward use variable, a type of binary variable used to enforce forward directionality in reaction net fluxes

prefix = `FU_`

`pytfa.analysis.get_bistream_logger`(*name*)

Sets up a logger that outputs INFO+ messages on stdout and DEBUG+ messages in the log file

Parameters

name – a class `__name__` attribute

Returns

`pytfa.analysis.CPU_COUNT`

`pytfa.analysis.BEST_THREAD_RATIO`

`pytfa.analysis.find_bidirectional_reactions`(*va*, *tolerance=1e-08*)

Returns the ids of reactions that can both carry net flux in the forward or backward direction.

Parameters

va –

A variability analysis, pandas Dataframe like so:
 maximum minimum

```
6PGLter -8.330667e-04 -8.330667e-04 ABUTt2r 0.000000e+00 0.000000e+00 ACALDt
0.000000e+00 0.000000e+00
```

Returns

`pytfa.analysis.find_directionality_profiles`(*tmodel*, *bidirectional*, *max_iter=10000.0*,
solver='optlang-glpk')

Takes a ThermoModel and performs enumeration of the directionality profiles

Parameters

- **tmodel** –
- **max_iter** –

Returns

`pytfa.analysis._bool2str`(*bool_list*)

turns a list of booleans into a string

Parameters

bool_list – ex: '[False True False False True]'

Returns

'01001'

`pytfa.analysis._variability_analysis_element`(*tmodel*, *var*, *sense*)

`pytfa.analysis.variability_analysis`(*tmodel*, *kind='reactions'*, *proc_num=BEST_THREAD_RATIO*)

Performs variability analysis, given a variable type

Parameters

- **tmodel** –
- **kind** –
- **proc_num** –

Returns

`pytfa.analysis.parallel_variability_analysis`(*tmodel*, *kind='reactions'*,
proc_num=BEST_THREAD_RATIO)

WIP.

Parameters

- **tmodel** –
- **kind** –
- **proc_num** –

Returns

`pytfa.analysis.calculate_dissipation`(*tmodel*, *solution=None*)

`pytfa.analysis.apply_reaction_variability`(*tmodel*, *va*, *inplace=True*)

Applies the VA results as bounds for the reactions of a cobra_model :param inplace: :param tmodel: :param va:
:return:

`pytfa.analysis.apply_generic_variability`(*tmodel*, *va*, *inplace=True*)

Reactions a dealt with cobra, but the other variables added use pytfa's interface: the class GenericVariable. We use a different method to apply variability directly in the solver

Parameters

- **tmodel** –
- **va** –
- **inplace** –

Returns

`pytfa.analysis.apply_directionality(tmodel, solution, inplace=True)`

Takes a flux solution and transfers its reaction directionality as constraints for the cobra_model

Parameters

- **inplace** –
- **tmodel** –
- **solution** –

Returns

`pytfa.core`

`pytfa.io`

Submodules

`pytfa.io.base`

Input/Output tools to import or export pytfa models

Module Contents

Functions

<code>import_matlab_model(path, variable_name=None)</code>	Convert a matlab cobra_model to a pyTFA cobra_model, with Thermodynamic values
<code>recover_compartments(model, compartments_list)</code>	
<code>write_matlab_model(tmodel, path, var_name='tmodel')</code>	Writes the Thermo Model to a Matlab-compatible structure
<code>create_thermo_dict(tmodel)</code>	Dumps the thermodynamic information in a mat-compatible dictionary
<code>varnames2matlab(name, tmodel)</code>	Transforms reaction variable pairs from ('ACALD', 'ACALD_reverse_xxxx') to
<code>create_problem_dict(tmodel)</code>	Dumps the the MILP formulation for TFA in a mat-compatible dictionary
<code>create_generalized_matrix(tmodel, array_type='dense')</code>	Returns the generalized stoichiometric matrix used for TFA
<code>load_thermoDB(path)</code>	Load a thermodynamic database
<code>printLP(model)</code>	Print the LP file corresponding to the cobra_model
<code>writeLP(model, path=None)</code>	Write the LP file of the specified cobra_model to the file indicated by path.

`pytfa.import_matlab_model(path, variable_name=None)`

Convert at matlab cobra_model to a pyTFA cobra_model, with Thermodynamic values

Parameters

- **variable_name** –
- **path** (*string*) – The path of the file to import

Returns

The converted cobra_model

Return type

cobra.thermo.model.Model

`pytfa.recover_compartments(model, compartments_list)`

`pytfa.write_matlab_model(tmodel, path, varname='tmodel')`

Writes the Thermo Model to a Matlab-compatible structure

Parameters

- **varname** –
- **tmodel** –
- **path** –

Returns

None

`pytfa.create_thermo_dict(tmodel)`

Dumps the thermodynamic information in a mat-compatible dictionary (similar to the output of cobra.io.mat.create_mat_dict)

Parameters

tmodel – pytfa.thermo.tmodel.ThermoModel

Returns

dict object

`pytfa.varnames2matlab(name, tmodel)`

Transforms reaction variable pairs from ('ACALD', 'ACALD_reverse_xxxx') to ('F_ACALD', 'B_ACALD') if it is a reaction, else leaves is as is

Returns

`pytfa.create_problem_dict(tmodel)`

Dumps the the MILP formulation for TFA in a mat-compatible dictionary (similar to the output of cobra.io.mat.create_mat_dict)

Parameters

tmodel – pytfa.thermo.tmodel.ThermoModel

:ret

`pytfa.create_generalized_matrix(tmodel, array_type='dense')`

Returns the generalized stoichiometric matrix used for TFA

Parameters

- **array_type** –
- **tmodel** – pytfa.ThermoModel

Returns

matrix.

`pytfa.load_thermoDB(path)`

Load a thermodynamic database

Parameters

path (*string*) – The path of the file to load

Returns

The thermodynamic database

Return type

dict

`pytfa.printLP(model)`

Print the LP file corresponding to the cobra_model

Parameters

model (*cobra.thermo.model.Model*) – The cobra_model to output the LP file for

Returns

The content of the LP file

Return type

str

Usually, you pass the result of this function to `file.write()` to write it on disk. If you prefer, you can use `pytfa.io.writeLP()` to write the result directly to a file.

`pytfa.writeLP(model, path=None)`

Write the LP file of the specified cobra_model to the file indicated by path.

Parameters

- **model** (*cobra.thermo.model.Model*) – The COBRApy cobra_model to write the LP file for
- **path** (*string*) – *Optional* The path of the file to be written. If not specified, the name of the COBRApy cobra_model will be used.

`pytfa.io.dict`

Make the model serializable

' b3991': defaultdict(int,

```

```
{'ala__L_c': -42,
  'arg__L_c': -11, 'asn__L_c': -6,
  ... })
```

`pytfa.get_solver_string(model)`

`pytfa.obj_to_dict(model)`

`pytfa.model_to_dict(model)`

Parameters

`model` –

Returns

`pytfa._add_thermo_reaction_info(rxn, rxn_dict)`

`pytfa._add_thermo_metabolite_info(met, met_dict)`

`pytfa.model_from_dict(obj, solver=None, custom_hooks=None)`

Custom_hooks looks like

```
custom_hooks = {<EnzymeVariable Class at 0xfffff> : 'enzymes',
  ... }
```

Parameters

- `obj` –
- `solver` –
- `custom_hooks` –

Returns

`pytfa.rebuild_obj_from_dict(new, objective_dict)`

`pytfa.add_custom_classes(model, custom_hooks)`

Allows custom variable serialization

Parameters

- `model` –
- `base_classes` –
- `base_hooks` –
- `custom_hooks` –

Returns

`pytfa.get_hook_dict(model, custom_hooks)`

`pytfa.init_thermo_model_from_dict(new, obj)`

`pytfa.rebuild_compositions(new, compositions_dict)`

Performs the reverse operation of `:func:archive_compositions`

Parameters

- `new` –

- `compositions_dict` –

Returns

`pytfa._rebuild_stoichiometry(new, stoich)`

Performs the reverse operation of `:func:_stoichiometry_to_dict`

Parameters

- `new` –
- `stoich` –

Returns

`pytfa.io.enrichment`

Tools to import or export enrichment to and from pytfa models

Module Contents

Functions

<code>write_lexicon(tmodel, filepath)</code>	Writes a csv file in the format :
<code>annotate_from_lexicon(model, lexicon)</code>	Converts a lexicon into annotation for the metabolites
<code>read_lexicon(filepath)</code>	
<code>write_compartment_data(tmodel, filepath)</code>	param filepath
<code>read_compartment_data(filepath)</code>	
<code>apply_compartment_data(tmodel, compartment_data)</code>	

`pytfa.write_lexicon(tmodel, filepath)`

Writes a csv file in the format :

seed_id

13BDgln_c cpd11791 13dpg_c cpd00203 2pg_c cpd00482 3pg_c cpd00169 4abut_c cpd00281

Useful for exporting an annotation

Parameters

- `tmodel` (`pytfa.core.ThermoModel`) –
- `filepath` –

Returns

`pytfa.annotate_from_lexicon(model, lexicon)`

Converts a lexicon into annotation for the metabolites

Parameters

- `model` (`cobra.Model`) –

- **lexicon** –

Returns

`pytfa.read_lexicon(filepath)`

`pytfa.write_compartment_data(tmodel, filepath)`

Parameters

- **filepath** –
- **tmodel** (`pytfa.core.ThermoModel`) –

Returns

`pytfa.read_compartment_data(filepath)`

`pytfa.apply_compartment_data(tmodel, compartment_data)`

`pytfa.io.json`

JSON serialization

Module Contents

Classes

<code>MyEncoder</code>	We define an encoder that takes care of the serialization of numpy types,
------------------------	---

Functions

<code>check_json_extension(filepath)</code>	
<code>save_json_model(model, filepath)</code>	
<code>load_json_model(filepath)</code>	
<code>json_dumps_model(model)</code>	Returns a JSON dump as a string
<code>json_loads_model(s)</code>	Loads a model from a string JSON dump

class `pytfa.MyEncoder`(*, *skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, sort_keys=False, indent=None, separators=None, default=None*)

Bases: `json.JSONEncoder`

We define an encoder that takes care of the serialization of numpy types, which are not handled by json by default

default(*self*, *obj*)

Implement this method in a subclass such that it returns a serializable object for *o*, or calls the base implementation (to raise a `TypeError`).

For example, to support arbitrary iterators, you could implement `default` like this:

```
def default(self, o):
    try:
        iterable = iter(o)
    except TypeError:
        pass
    else:
        return list(iterable)
    # Let the base class default method raise the TypeError
    return JSONEncoder.default(self, o)
```

`pytfa.check_json_extension(filepath)`

`pytfa.save_json_model(model, filepath)`

`pytfa.load_json_model(filepath)`

`pytfa.json_dumps_model(model)`

Returns a JSON dump as a string

Parameters

`model` –

Returns

`pytfa.json_loads_model(s)`

Loads a model from a string JSON dump

Parameters

`s` – JSON string

Returns

`pytfa.io.plotting`

Plotting results

Module Contents

Functions

`plot_fva_tva_comparison(fva, tva)`

<code>plot_thermo_displacement_histogram(tmodel, solution=None)</code>	Plot a histogram of the thermodynamic displacement. if no solution is
--	---

<code>plot_histogram(values, **kwargs)</code>	Convenience function. Plots a histogram of flat 1D data.
---	--

`pytfa.plot_fva_tva_comparison(fva, tva)`

`pytfa.plot_thermo_displacement_histogram(tmodel, solution=None)`

Plot a histogram of the thermodynamic displacement. if no solution is provided, will look at the cobra_model's own solution

Parameters

- `tmodel` –
- `solution` –

Returns

`pytfa.plot_histogram(values, **kwargs)`

Convenience function. Plots a histogram of flat 1D data.

Parameters

`values` –

Returns

`pytfa.io.viz`

Input/Output tools to visualize results

Module Contents

Functions

<code>export_variable_for_escher(tmodel, variable_type, data, filename)</code>	vari-	Exports all the variables of a given type into a csv file, indexed by
<code>get_reaction_data(tmodel, data)</code>		Exports values indexed by reaction ids. Reconciles Forward and Backwards
<code>export_reactions_for_escher(tmodel, data, filename)</code>	file-	Exports values indexed by reaction ids. Reconciles Forward and Backwards

`pytfa.export_variable_for_escher(tmodel, variable_type, data, filename)`

Exports all the variables of a given type into a csv file, indexed by variable.id. This format is readable by escher if the variable_type is a subclass of `:pytfa:pytfa.optim.variables.ReactionVariable`` or `:pytfa:pytfa.optim.variables.MetaboliteVariable``

Parameters

- `tmodel` (`pytfa.core.ThermoModel`) –
- `variable_type` (`ReactionVariable`/`MetaboliteVariable`) –
- `data` (`pandas.Series`) – indexed by variable name
- `filename` (`string`) –

Returns

`pytfa.get_reaction_data(tmodel, data)`

Exports values indexed by reaction ids. Reconciles Forward and Backwards variables.

`pytfa.export_reactions_for_escher(tmodel, data, filename)`

Exports values indexed by reaction ids. Reconciles Forward and Backwards variables. Writes it in a csv file. This format is readable by escher

Parameters

- **tmodel** (*pytfa.core.ThermoModel*) –
- **variable_type** (*ReactionVariable/MetaboliteVariable*) –
- **data** (*pandas.Series*) – indexed by variable name
- **filename** (*string*) –

Returns

Package Contents

Classes

<code>import_matlab_model(path, variable_name=None)</code>	Convert at matlab cobra_model to a pyTFA cobra_model, with Thermodynamic values
<code>recover_compartments(model, compartments_list)</code>	
<code>write_matlab_model(tmodel, path, variable_name='tmodel')</code>	Writes the Thermo Model to a Matlab-compatible structure
<code>create_thermo_dict(tmodel)</code>	Dumps the thermodynamic information in a mat-compatible dictionary
<code>varnames2matlab(name, tmodel)</code>	Transforms reaction variable pairs from ('ACALD', 'ACALD_reverse_xxxx') to
<code>create_problem_dict(tmodel)</code>	Dumps the the MILP formulation for TFA in a mat-compatible dictionary
<code>create_generalized_matrix(tmodel, array_type='dense')</code>	Returns the generalized stoichiometric matrix used for TFA
<code>load_thermoDB(path)</code>	Load a thermodynamic database
<code>printLP(model)</code>	Print the LP file corresponding to the cobra_model
<code>writeLP(model, path=None)</code>	Write the LP file of the specified cobra_model to the file indicated by path.
<code>write_lexicon(tmodel, filepath)</code>	Writes a csv file in the format :
<code>annotate_from_lexicon(model, lexicon)</code>	Converts a lexicon into annotation for the metabolites
<code>read_lexicon(filepath)</code>	
<code>write_compartment_data(tmodel, filepath)</code>	param filepath
<code>read_compartment_data(filepath)</code>	
<code>apply_compartment_data(tmodel, compartment_data)</code>	

Attributes

`BIGM_DG`

`pytfa.io.BIGM_DG = 1000.0`

`pytfa.io.import_matlab_model(path, variable_name=None)`

Convert at matlab cobra_model to a pyTFA cobra_model, with Thermodynamic values

Parameters

- **variable_name** –
- **path** (*string*) – The path of the file to import

Returns

The converted cobra_model

Return type

cobra.thermo.model.Model

`pytfa.io.recover_compartments(model, compartments_list)`

`pytfa.io.write_matlab_model(tmodel, path, varname='tmodel')`

Writes the Thermo Model to a Matlab-compatible structure

Parameters

- **varname** –
- **tmodel** –
- **path** –

Returns

None

`pytfa.io.create_thermo_dict(tmodel)`

Dumps the thermodynamic information in a mat-compatible dictionary (similar to the output of `cobra.io.mat.create_mat_dict`)

Parameters

tmodel – `pytfa.thermo.tmodel.ThermoModel`

Returns

dict object

`pytfa.io.varnames2matlab(name, tmodel)`

Transforms reaction variable pairs from ('ACALD', 'ACALD_reverse_xxxx') to ('F_ACALD', 'B_ACALD') if it is a reaction, else leaves is as is

Returns

`pytfa.io.create_problem_dict(tmodel)`

Dumps the the MILP formulation for TFA in a mat-compatible dictionary (similar to the output of `cobra.io.mat.create_mat_dict`)

Parameters

tmodel – `pytfa.thermo.tmodel.ThermoModel`

:ret

`pytfa.io.create_generalized_matrix(tmodel, array_type='dense')`

Returns the generalized stoichiometric matrix used for TFA

Parameters

- **array_type** –
- **tmodel** – `pytfa.ThermoModel`

Returns

matrix.

`pytfa.io.load_thermoDB(path)`

Load a thermodynamic database

Parameters

path (*string*) – The path of the file to load

Returns

The thermodynamic database

Return type

dict

`pytfa.io.printLP(model)`

Print the LP file corresponding to the `cobra_model`

Parameters

model (`cobra.thermo.model.Model`) – The `cobra_model` to output the LP file for

Returns

The content of the LP file

Return type

`str`

Usually, you pass the result of this function to `file.write()` to write it on disk. If you prefer, you can use `pytfa.io.writeLP()` to write the result directly to a file.

`pytfa.io.writeLP(model, path=None)`

Write the LP file of the specified `cobra_model` to the file indicated by `path`.

Parameters

- **model** (`cobra.thermo.model.Model`) – The COBRApy `cobra_model` to write the LP file for
- **path** (`string`) – *Optional* The path of the file to be written. If not specified, the name of the COBRApy `cobra_model` will be used.

class `pytfa.io.MyEncoder`(*, `skipkeys=False`, `ensure_ascii=True`, `check_circular=True`, `allow_nan=True`, `sort_keys=False`, `indent=None`, `separators=None`, `default=None`)

Bases: `json.JSONEncoder`

We define an encoder that takes care of the serialization of numpy types, which are not handled by json by default

default(`self, obj`)

Implement this method in a subclass such that it returns a serializable object for `o`, or calls the base implementation (to raise a `TypeError`).

For example, to support arbitrary iterators, you could implement `default` like this:

```
def default(self, o):
    try:
        iterable = iter(o)
    except TypeError:
        pass
    else:
        return list(iterable)
    # Let the base class default method raise the TypeError
    return JSONEncoder.default(self, o)
```

`pytfa.io.write_lexicon(tmodel, filepath)`

Writes a csv file in the format :

seed_id

13BDgln_c cpd11791 13dpg_c cpd00203 2pg_c cpd00482 3pg_c cpd00169 4abut_c cpd00281

Useful for exporting an annotation

Parameters

- **tmodel** (`pytfa.core.ThermoModel`) –

- **filepath** –

Returns

`pytfa.io.annotate_from_lexicon(model, lexicon)`

Converts a lexicon into annotation for the metabolites

Parameters

- **model** (*cobra.Model*) –
- **lexicon** –

Returns

`pytfa.io.read_lexicon(filepath)`

`pytfa.io.write_compartment_data(tmodel, filepath)`

Parameters

- **filepath** –
- **tmodel** (*pytfa.core.ThermoModel*) –

Returns

`pytfa.io.read_compartment_data(filepath)`

`pytfa.io.apply_compartment_data(tmodel, compartment_data)`

`pytfa.optim`

Submodules

`pytfa.optim.config`

Pre-tuned configurations for faster solving

Module Contents

Functions

`dg_relax_config(model)`

param model

`pytfa.dg_relax_config(model)`

Parameters

- model** –

Returns

pytfa.optim.constraints

Constraints declarations

Module Contents

Classes

GenericConstraint	Class to represent a generic constraint. The purpose is that the interface
ModelConstraint	Class to represent a variable attached to the model
GeneConstraint	Class to represent a variable attached to an enzyme
ReactionConstraint	Class to represent a variable attached to a reaction
MetaboliteConstraint	Class to represent a variable attached to an enzyme
NegativeDeltaG	Class to represent thermodynamics constraints.
ForwardDeltaGCoupling	Class to represent thermodynamics coupling: DeltaG of reactions has to be
BackwardDeltaGCoupling	Class to represent thermodynamics coupling: DeltaG of reactions has to be
ForwardDirectionCoupling	Class to represent a forward directionality coupling with thermodynamics on
BackwardDirectionCoupling	Class to represent a backward directionality coupling with thermodynamics on
SimultaneousUse	Class to represent a simultaneous use constraint on reaction variables
DisplacementCoupling	Class to represent the coupling to the thermodynamic displacement
ForbiddenProfile	Class to represent a forbidden net flux directionality profile
LinearizationConstraint	Class to represent a variable attached to a reaction

class pytfa.GenericConstraint(*expr*, *id_=""*, *model=None*, *hook=None*, *queue=False*, ***kwargs*)

Class to represent a generic constraint. The purpose is that the interface

is instantiated on initialization, to follow the type of interface used by the problem, and avoid incompatibilities in optlang

Attributes:

id

Used for DictList comprehension. Usually points back at a

enzyme or reaction id for ease of linking. Should be unique given a constraint type. *:name:* Should be a concatenation of the id and a prefix that is specific to the variable type. will be used to address the constraint at the solver level, and hence should be unique in the whole cobra_model *:expr:* the expression of the constraint (sympy.Expression subtype) *:cobra_model:* the cobra_model hook. *:constraint:* links directly to the cobra_model representation of the constraint

prefix

property __attrname__(*self*)

Name the attribute the instances will have Example: GenericConstraint -> generic_constraint :return:

get_interface(*self*, *expr*, *queue*)

Called upon completion of `__init__`, initializes the value of `self.var`, which is returned upon call, and stores the actual interfaced variable.

Returns

instance of Variable from the problem

make_name(*self*)

Needs to be overridden by the subclass, concatenates the id with a prefix

Returns

None

change_expr(*self*, *new_expr*, *sloppy=False*)

property expr(*self*)

property name(*self*)

property id(*self*)

for cobra.thermo.DictList compatibility :return:

property constraint(*self*)

property model(*self*)

__repr__(*self*)

Return repr(self).

class pytfa.**ModelConstraint**(*model*, *expr*, *id_*, ***kwargs*)

Bases: [GenericConstraint](#)

Class to represent a variable attached to the model

prefix = MODC_

class pytfa.**GeneConstraint**(*gene*, *expr*, ***kwargs*)

Bases: [GenericConstraint](#)

Class to represent a variable attached to an enzyme

prefix = GC_

property gene(*self*)

property id(*self*)

for cobra.thermo.DictList compatibility :return:

property model(*self*)

class pytfa.**ReactionConstraint**(*reaction*, *expr*, ***kwargs*)

Bases: [GenericConstraint](#)

Class to represent a variable attached to a reaction

prefix = RC_

property reaction(*self*)

property `id(self)`
 for cobra.thermo.DictList compatibility :return:

property `model(self)`

class `pytfa.MetaboliteConstraint(metabolite, expr, **kwargs)`

Bases: *GenericConstraint*

Class to represent a variable attached to a enzyme

prefix = `MC_`

property `metabolite(self)`

property `id(self)`
 for cobra.thermo.DictList compatibility :return:

property `model(self)`

class `pytfa.NegativeDeltaG(reaction, expr, **kwargs)`

Bases: *ReactionConstraint*

Class to represent thermodynamics constraints.

G: $-DGR_{rxn} + DGoRerr_{Rxn} + RT * StoichCoefProd1 * LC_{prod1}$

- $RT * StoichCoefProd2 * LC_{prod2}$
- $RT * StoichCoefSub1 * LC_{subs1}$
- $RT * StoichCoefSub2 * LC_{subs2}$
- ...

= 0

prefix = `G_`

class `pytfa.ForwardDeltaGCoupling(reaction, expr, **kwargs)`

Bases: *ReactionConstraint*

Class to represent thermodynamics coupling: DeltaG of reactions has to be $DGR < 0$ for the reaction to proceed forwards Looks like: $FU_{rxn}: 1000 FU_{rxn} + DGR_{rxn} < 1000$

prefix = `FU_`

class `pytfa.BackwardDeltaGCoupling(reaction, expr, **kwargs)`

Bases: *ReactionConstraint*

Class to represent thermodynamics coupling: DeltaG of reactions has to be $DGR > 0$ for the reaction to proceed backwards Looks like: $BU_{rxn}: 1000 BU_{rxn} - DGR_{rxn} < 1000$

prefix = `BU_`

class `pytfa.ForwardDirectionCoupling(reaction, expr, **kwargs)`

Bases: *ReactionConstraint*

Class to represent a forward directionality coupling with thermodynamics on reaction variables Looks like : $UF_{rxn}: F_{rxn} - M FU_{rxn} < 0$

prefix = `UF_`

class pytfa.**BackwardDirectionCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent a backward directionality coupling with thermodynamics on reaction variables Looks like :
 $UR_{rxn}: R_{rxn} - M RU_{rxn} < 0$

prefix = UR_

class pytfa.**SimultaneousUse**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent a simultaneous use constraint on reaction variables Looks like: $SU_{rxn}: FU_{rxn} + BU_{rxn} \leq 1$

prefix = SU_

class pytfa.**DisplacementCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent the coupling to the thermodynamic displacement Looks like: $Ln(\Gamma) - (1/RT)*DGR_{rxn} = 0$

prefix = DC_

class pytfa.**ForbiddenProfile**(*model, expr, id_, **kwargs*)

Bases: *GenericConstraint*

Class to represent a forbidden net flux directionality profile Looks like: $FU_{rxn_1} + BU_{rxn_2} + \dots + FU_{rxn_n} \leq n-1$

prefix = FP_

class pytfa.**LinearizationConstraint**(*model, expr, id_, **kwargs*)

Bases: *ModelConstraint*

Class to represent a variable attached to a reaction

prefix = LC_

static from_constraints(*cons, model*)

pytfa.optim.debugging

Debugging of models

Module Contents

Functions

<code>debug_iis(model)</code>	Performs reduction to an Irreducible Inconsistent Sub-system (IIS)
<code>find_extreme_coeffs(model, n=5)</code>	
<code>find_maxed_vars(model, ub=1000, epsilon=0.01)</code>	

`pytfa.debug_iis(model)`

Performs reduction to an Irreducible Inconsistent Subsystem (IIS)

Parameters

`model` –

Returns

`pytfa.find_extreme_coeffs(model, n=5)`

`pytfa.find_maxed_vars(model, ub=1000, epsilon=0.01)`

pytfa.optim.meta

Metaclass declarations to force the definition of prefixes in GenericVariable and GeneriConstraint subclasses

Based on SethMMorton's answer on StackOverflow <https://stackoverflow.com/questions/45248243/most-pythonic-way-to-declare-an-abstract-class-property> <https://stackoverflow.com/a/45250114>

Module Contents

Classes

<code>RequirePrefixMeta</code>	Metaclass that enforces child classes define prefix.
--------------------------------	--

Attributes

<code>ABCRequirePrefixMeta</code>

class `pytfa.RequirePrefixMeta`(*cls, name, bases, attrs*)

Bases: `type`

Metaclass that enforces child classes define prefix.

`pytfa.ABCRequirePrefixMeta`

pytfa.optim.reformulation

MILP-fu to reformulate problems

Module Contents

Functions

<code>subs_bilinear(expr)</code>	Substitutes bilinear forms from an expression with dedicated variables
<code>glovers_linearization(b, fy, z=None, L=0, U=1000)</code>	Glover, Fred.
<code>petersen_linearization(b, x, z=None, M=1000)</code>	PETERSEN, C.,
<code>linearize_product(model, b, x, queue=False)</code>	param model

Attributes

<code>ConstraintTuple</code>
<code>OPTLANG_BINARY</code>

`pytfa.ConstraintTuple`

`pytfa.OPTLANG_BINARY = binary`

`pytfa.subs_bilinear(expr)`

Substitutes bilinear forms from an expression with dedicated variables :param expr: :return:

`pytfa.glovers_linearization(b, fy, z=None, L=0, U=1000)`

Glover, Fred. "Improved linear integer programming formulations of nonlinear integer problems." Management Science 22.4 (1975): 455-460.

Performs Glovers Linearization of a product $z = b*f(y) \Leftrightarrow z - b*f(y) = 0 \Leftrightarrow \{ L*b \leq z \leq U*b \mid f(y) - U*(1-b) \leq z \leq f(y) - L*(1-b)$

where : * b is a binary variable * f a linear combination of continuous or integer variables y

Parameters

- **b** – Must be a binary optlang variable
- **z** – Must be an optlang variable. Will be mapped to the product so that $z = b*f(y)$
- **fy** – Must be an expression or variable
- **L** – minimal value for fy
- **U** – maximal value for fy

Returns

`pytfa.petersen_linearization(b, x, z=None, M=1000)`

PETERSEN, C., "A Note on Transforming the Product of Variables to Linear Form in Linear CLIFFORD Programs," Working Paper, Purdue University, 1971.

Performs Petersen Linearization of a product $z = b*x \Leftrightarrow z - b*x = 0 \Leftrightarrow \{ x + M*b - M \leq z \leq M*b \mid z \leq x$

where : * b is a binary variable * f a linear combination of continuous or integer variables y

Parameters

- **x** – Must be an expression or variable
- **b** – Must be a binary optlang variable
- **z** – Must be an optlang variable. Will be mapped to the product so that $z = b * f(y)$
- **M** – big-M constraint

Returns

`pytfa.linearize_product(model, b, x, queue=False)`

Parameters

- **model** –
- **b** – the binary variable
- **x** – the continuous variable
- **queue** – whether to queue the variables and constraints made

Returns**pytfa.optim.relaxation**

Relaxation of models with constraint too tight

Module Contents**Functions**

`relax_dgo_gurobi(model, relax_obj_type=0)`

`relax_dgo(tmodel, reactions_to_ignore=(), solver=None, in_place=False)` **param t_model**

`relax_lc(tmodel, metabolites_to_ignore=(), solver=None)` **param metabolites_to_ignore**

Attributes

BIGM

BIGM_THERMO

BIGM_DG

BIGM_P

EPSILON

pytfa.BIGM

pytfa.BIGM_THERMO

pytfa.BIGM_DG

pytfa.BIGM_P

pytfa.EPSILON

pytfa.relax_dgo_gurobi(*model*, *relax_obj_type=0*)

pytfa.relax_dgo(*tmodel*, *reactions_to_ignore=()*, *solver=None*, *in_place=False*)

Parameters

- **t_tmodel** (*pytfa.thermo.ThermoModel:*) –
- **reactions_to_ignore** – Iterable of reactions that should not be relaxed
- **solver** – solver to use (e.g. ‘optlang-glpk’, ‘optlang-cplex’, ‘optlang-gurobi’)

Returns

a cobra_model with relaxed bounds on standard Gibbs free energy

pytfa.relax_lc(*tmodel*, *metabolites_to_ignore=()*, *solver=None*)

Parameters

- **metabolites_to_ignore** –
- **in_tmodel** (*pytfa.thermo.ThermoModel:*) –
- **min_objective_value** –

Returns

pytfa.optim.utils

Relaxation of models with constraint too tight

Module Contents

Functions

<code>get_all_subclasses(cls)</code>	Given a variable or constraint class, get all the subclasses
<code>chunk_sum(variables)</code>	This functions handles the sum of many sympy variables by chunks, which
<code>symbol_sum(variables)</code>	``` python
<code>get_solution_value_for_variables(solution, these_vars, index_by_reaction=False)</code>	
<code>compare_solutions(models)</code>	returns the solution dictionary for each cobra_model
<code>evaluate_constraint_at_solution(constraint, solution)</code>	param expression
<code>get_active_use_variables(tmodel, solution)</code>	Returns the active use variables in a solution. Use Variables are binary
<code>get_direction_use_variables(tmodel, solution)</code>	Returns the active use variables in a solution. Use Variables are binary
<code>get_primal(tmodel, vartype, index_by_reactions=False)</code>	Returns the primal value of the cobra_model for variables of a given type
<code>strip_from_integer_variables(tmodel)</code>	Removes all integer and binary variables of a cobra_model, to make it sample-able
<code>copy_solver_configuration(source, target)</code>	Copies the solver configuration from a source model to a target model

Attributes

SYMPY_ADD_CHUNKSIZE

INTEGER_VARIABLE_TYPES

`pytfa.SYMPY_ADD_CHUNKSIZE = 100`

`pytfa.INTEGER_VARIABLE_TYPES = ['binary', 'integer']`

`pytfa.get_all_subclasses(cls)`

Given a variable or constraint class, get all the subclasses that inherit from it

Parameters

`cls` –

Returns

`pytfa.chunk_sum(variables)`

This functions handles the sum of many sympy variables by chunks, which somehow increases the speed of the computation

You can test it in IPython: ```python a = sympy.symbols('a0:100') %timeit (sum(a)) # >>> 198 μs ± 11.4 μs per loop (mean ± std. dev. of 7 runs, 1 loop each)

b = sympy.symbols('b0:1000') %timeit (sum(b)) # >>> 1.85 ms ± 356 μs per loop (mean ± std. dev. of 7 runs, 1 loop each)

```
c = sympy.symbols('c0:3000') %timeit (sum(c)) # >>> 5min 7s ± 2.57 s per loop (mean ± std. dev. of 7 runs, 1 loop each) """
```

See the [github thread](#)

Parameters
variables –

Returns

`pytfa.symbol_sum(variables)`

```
""" python a = symbols('a0:100')
%timeit Add(*a) # >>> 10000 loops, best of 3: 34.1 µs per loop
b = symbols('b0:1000')
%timeit Add(*b) # >>> 1000 loops, best of 3: 343 µs per loop
c = symbols('c0:3000')
%timeit Add(*c) # >>> 1 loops, best of 3: 1.03 ms per loop """
```

See the [github thread](#) :param variables: :return:

`pytfa.get_solution_value_for_variables(solution, these_vars, index_by_reaction=False)`

`pytfa.compare_solutions(models)`

returns the solution dictionary for each cobra_model :param (iterable (pytfa.thermo.ThermoModel)) models:
:return:

`pytfa.evaluate_constraint_at_solution(constraint, solution)`

Parameters

- **expression** –
- **solution** – pandas.DataFrame, with index as variable names

Returns

`pytfa.get_active_use_variables(tmodel, solution)`

Returns the active use variables in a solution. Use Variables are binary variables that control the directionality of the reaction

ex: FU_ACALDt BU_PFK

Parameters

- **tmodel** (`pytfa.core.ThermoModel`) –
- **solution** –

Returns

`pytfa.get_direction_use_variables(tmodel, solution)`

Returns the active use variables in a solution. Use Variables are binary variables that control the directionality of the reaction The difference with `get_active_use_variables` is that variables with both UseVariables at 0 will return as going forwards. This is to ensure that the output size of the function is equal to the number of FDPs

ex: FU_ACALDt BU_PFK

Parameters

- **tmodel** (`pytfa.core.ThermoModel`) –

- **solution** –

Returns

`pytfa.get_primal(tmodel, vartype, index_by_reactions=False)`

Returns the primal value of the cobra_model for variables of a given type :param tmodel: :param vartype: Class of variable. Ex: `pytfa.optim.variables.ThermoDisplacement` :param index_by_reactions: Set to true to get reaction names as index instead of

variables. Useful for Escher export

Returns

`pytfa.strip_from_integer_variables(tmodel)`

Removes all integer and binary variables of a cobra_model, to make it sample-able :param tmodel: :return:

`pytfa.copy_solver_configuration(source, target)`

Copies the solver configuration from a source model to a target model :param source: :param target: :return:

`pytfa.optim.variables`

get_binary_type()	FIX : We enforce type to be integer instead of binary, else optlang does
-------------------	--

Attributes

op_replace_dict

pytfa.op_replace_dict

class pytfa.GenericVariable(*id*="", *model*=None, *hook*=None, *queue*=False, *scaling_factor*=1, ***kwargs*)

Class to represent a generic variable. The purpose is that the interface is instantiated on initialization, to follow the type of interface used by the problem, and avoid incompatibilities in optlang

Attributes:

id

Used for DictList comprehension. Usually points back at a

enzyme or reaction id for ease of linking. Should be unique given a variable type. :name: Should be a concatenation of the id and a prefix that is specific to the variable type. will be used to address the variable at the solver level, and hence should be unique in the whole cobra_model :cobra_model: the cobra_model hook. :variable: links directly to the cobra_model representation of the variable

prefix**property** `__attrname__(self)`

Name the attribute the instances will have Example: GenericVariable -> generic_variable :return:

get_interface(self, queue)

Called upon completion of `__init__`, initializes the value of self.var, which is returned upon call, and stores the actual interfaced variable.

Returns

instance of Variable from the problem

make_name(self)

Needs to be overridden by the subclass, concatenates the id with a prefix

Returns

None

property `name(self)`**property** `id(self)`

for cobra.thermo.DictList compatibility :return:

property `variable(self)`**property** `scaling_factor(self)`**property** `unscaled(self)`

If the scaling factor of quantity X is a, it is represented by the variable $X_{\text{hat}} = X/a$. This returns $X = a \cdot X_{\text{hat}}$ Useful for nondimensionalisation of variables and constraints

Returns

The variable divided by its scaling factor

property `value(self)`**property** `unscaled_value(self)`**property** `model(self)`**property** `type(self)`**test_consistency**(self, other)

Tests whether a candidate to an operation is of the right type and is from the same problem

Parameters

other – an object

Returns

None

get_operand(*self*, *other*)

For operations, choose if the operand is a GenericVariable, in which we return its optlang variable, or something else (presumably a numeric) and we let optlang decide what to do

Parameters

other –

Returns

__add__(*self*, *other*)

Adding either two variables together or a variable and a numeric results in a new variable :param other:
:return: a new Generic Variable

__radd__(*self*, *other*)

Take priority on symmetric arithmetic operation :param other: :return:

__sub__(*self*, *other*)

Subtracting either two variables together or a variable and a numeric results in a new variable :param other:
:return: a new Generic Variable

__rsub__(*self*, *other*)

Take priority on symmetric arithmetic operation :param other: :return:

__mul__(*self*, *other*)

Multiplying either two variables together or a variable and a numeric results in a new variable :param other:
:return: a new Generic Variable

__rmul__(*self*, *other*)

Take priority on symmetric arithmetic operation :param other: :return:

__truediv__(*self*, *other*)

Dividing either two variables together or a variable and a numeric results in a new variable :param other:
:return: a new Generic Variable

__rtruediv__(*self*, *other*)

Take priority on symmetric arithmetic operation :param other: :return:

make_result(*self*, *new_variable*)

Returns a Sympy expression :param new_variable: :return:

__repr__(*self*)

Return repr(self).

pytfa.get_binary_type()

FIX : We enforce type to be integer instead of binary, else optlang does not allow to set the binary variable bounds to anything other than (0,1) You might want to set it at (0,0) to enforce directionality for example

class **pytfa.ModelVariable**(*model*, *id_*, ****kwargs**)

Bases: *GenericVariable*

Class to represent a variable attached to the model

Functions

<code>camel2underscores(name)</code>	
<code>camel2underscores(name)</code>	
<code>get_binary_type()</code>	FIX : We enforce type to be integer instead of binary, else optlang does
<code>dg_relax_config(model)</code>	param model
<code>get_solution_value_for_variables(solution, these_vars, index_by_reaction=False)</code>	
<code>chunk_sum(variables)</code>	This functions handles the sum of many sympy variables by chunks, which
<code>symbol_sum(variables)</code>	``` python
<code>relax_dgo_gurobi(model, relax_obj_type=0)</code>	
<code>relax_dgo(tmodel, reactions_to_ignore=(), solver=None, in_place=False)</code>	param t_model
<code>relax_lc(tmodel, metabolites_to_ignore=(), solver=None)</code>	param metabolites_to_ignore
<code>get_all_subclasses(cls)</code>	Given a variable or constraint class, get all the subclasses
<code>chunk_sum(variables)</code>	This functions handles the sum of many sympy variables by chunks, which
<code>symbol_sum(variables)</code>	``` python
<code>get_solution_value_for_variables(solution, these_vars, index_by_reaction=False)</code>	
<code>compare_solutions(models)</code>	returns the solution dictionary for each cobra_model
<code>evaluate_constraint_at_solution(constraint, solution)</code>	param expression
<code>get_active_use_variables(tmodel, solution)</code>	Returns the active use variables in a solution. Use Variables are binary
<code>get_direction_use_variables(tmodel, solution)</code>	Returns the active use variables in a solution. Use Variables are binary
<code>get_primal(tmodel, vartype, index_by_reactions=False)</code>	Returns the primal value of the cobra_model for variables of a given type
<code>strip_from_integer_variables(tmodel)</code>	Removes all integer and binary variables of a cobra_model, to make it sample-able
<code>copy_solver_configuration(source, target)</code>	Copies the solver configuration from a source model to a target model

pytfa.optim.**camel2underscores**(*name*)

pytfa.optim.**ABCRequirePrefixMeta**

class pytfa.optim.**GenericConstraint**(*expr, id_="", model=None, hook=None, queue=False, **kwargs*)

Class to represent a generic constraint. The purpose is that the interface

is instantiated on initialization, to follow the type of interface used by the problem, and avoid incompatibilities in optlang

Attributes:

id

Used for DictList comprehension. Usually points back at a

enzyme or reaction id for ease of linking. Should be unique given a constraint type. *:name:* Should be a concatenation of the id and a prefix that is specific to the variable type. will be used to address the constraint at the solver level, and hence should be unique in the whole cobra_model *:expr:* the expression of the constraint (sympy.Expression subtype) *:cobra_model:* the cobra_model hook. *:constraint:* links directly to the cobra_model representation of the constraint

prefix

property **__attrname__**(*self*)

Name the attribute the instances will have Example: GenericConstraint -> generic_constraint *:return:*

get_interface(*self, expr, queue*)

Called upon completion of **__init__**, initializes the value of self.var, which is returned upon call, and stores the actual interfaced variable.

Returns

instance of Variable from the problem

make_name(*self*)

Needs to be overridden by the subclass, concatenates the id with a prefix

Returns

None

change_expr(*self*, *new_expr*, *sloppy=False*)

property expr(*self*)

property name(*self*)

property id(*self*)

for cobra.thermo.DictList compatibility :return:

property constraint(*self*)

property model(*self*)

__repr__(*self*)

Return repr(*self*).

class pytfa.optim.**ModelConstraint**(*model*, *expr*, *id_*, ***kwargs*)

Bases: *GenericConstraint*

Class to represent a variable attached to the model

prefix = MODC_

class pytfa.optim.**GeneConstraint**(*gene*, *expr*, ***kwargs*)

Bases: *GenericConstraint*

Class to represent a variable attached to a enzyme

prefix = GC_

property gene(*self*)

property id(*self*)

for cobra.thermo.DictList compatibility :return:

property model(*self*)

class pytfa.optim.**ReactionConstraint**(*reaction*, *expr*, ***kwargs*)

Bases: *GenericConstraint*

Class to represent a variable attached to a reaction

prefix = RC_

property reaction(*self*)

property id(*self*)

for cobra.thermo.DictList compatibility :return:

property model(*self*)

class pytfa.optim.**MetaboliteConstraint**(*metabolite, expr, **kwargs*)

Bases: *GenericConstraint*

Class to represent a variable attached to a enzyme

prefix = MC_

property *metabolite*(*self*)

property *id*(*self*)

for cobra.thermo.DictList compatibility :return:

property *model*(*self*)

class pytfa.optim.**NegativeDeltaG**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent thermodynamics constraints.

G: - DGR_rxn + DGoRerr_Rxn + RT * StoichCoefProd1 * LC_prod1

- RT * StoichCoefProd2 * LC_prod2
- RT * StoichCoefSub1 * LC_subs1
- RT * StoichCoefSub2 * LC_subs2
- ...

= 0

prefix = G_

class pytfa.optim.**ForwardDeltaGCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent thermodynamics coupling: DeltaG of reactions has to be DGR < 0 for the reaction to proceed forwards Looks like: FU_rxn: 1000 FU_rxn + DGR_rxn < 1000

prefix = FU_

class pytfa.optim.**BackwardDeltaGCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent thermodynamics coupling: DeltaG of reactions has to be DGR > 0 for the reaction to proceed backwards Looks like: BU_rxn: 1000 BU_rxn - DGR_rxn < 1000

prefix = BU_

class pytfa.optim.**ForwardDirectionCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent a forward directionality coupling with thermodynamics on reaction variables Looks like : UF_rxn: F_rxn - M FU_rxn < 0

prefix = UF_

class pytfa.optim.**BackwardDirectionCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent a backward directionality coupling with thermodynamics on reaction variables Looks like : UR_rxn: R_rxn - M RU_rxn < 0

prefix = UR_

class pytfa.optim.**SimultaneousUse**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent a simultaneous use constraint on reaction variables Looks like: SU_rxn: FU_rxn + BU_rxn <= 1

prefix = SU_

class pytfa.optim.**DisplacementCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent the coupling to the thermodynamic displacement Looks like: Ln(Gamma) - (1/RT)*DGR_rxn = 0

prefix = DC_

class pytfa.optim.**ForbiddenProfile**(*model, expr, id_, **kwargs*)

Bases: *GenericConstraint*

Class to represent a forbidden net flux directionality profile Looks like: FU_rxn_1 + BU_rxn_2 + ... + FU_rxn_n <= n-1

prefix = FP_

class pytfa.optim.**LinearizationConstraint**(*model, expr, id_, **kwargs*)

Bases: *ModelConstraint*

Class to represent a variable attached to a reaction

prefix = LC_

static from_constraints(*cons, model*)

pytfa.optim.**camel2underscores**(*name*)

pytfa.optim.**ABCRequirePrefixMeta**

pytfa.optim.**op_replace_dict**

class pytfa.optim.**GenericVariable**(*id_=""*, *model=None*, *hook=None*, *queue=False*, *scaling_factor=1*, ***kwargs*)

Class to represent a generic variable. The purpose is that the interface is instantiated on initialization, to follow the type of interface used by the problem, and avoid incompatibilities in optlang

Attributes:

id

Used for DictList comprehension. Usually points back at a

enzyme or reaction id for ease of linking. Should be unique given a variable type. :name: Should be a concatenation of the id and a prefix that is specific to the variable type. will be used to address the variable at the solver level, and hence should be unique in the whole cobra_model :cobra_model: the cobra_model hook. :variable: links directly to the cobra_model representation of the variable

prefix

property __attrname__(*self*)

Name the attribute the instances will have Example: GenericVariable -> generic_variable :return:

get_interface(*self*, *queue*)

Called upon completion of `__init__`, initializes the value of `self.var`, which is returned upon call, and stores the actual interfaced variable.

Returns

instance of Variable from the problem

make_name(*self*)

Needs to be overridden by the subclass, concatenates the id with a prefix

Returns

None

property name(*self*)

property id(*self*)

for cobra.thermo.DictList compatibility :return:

property variable(*self*)

property scaling_factor(*self*)

property unscaled(*self*)

If the scaling factor of quantity X is a, it is represented by the variable $X_{\text{hat}} = X/a$. This returns $X = a.X_{\text{hat}}$ Useful for nondimensionalisation of variables and constraints

Returns

The variable divided by its scaling factor

property value(*self*)

property unscaled_value(*self*)

property model(*self*)

property type(*self*)

test_consistency(*self*, *other*)

Tests whether a candidate to an operation is of the right type and is from the same problem

Parameters

other – an object

Returns

None

get_operand(*self*, *other*)

For operations, choose if the operand is a GenericVariable, in which we return its optlang variable, or something else (presumably a numeric) and we let optlang decide what to do

Parameters

other –

Returns

__add__(*self*, *other*)

Adding either two variables together or a variable and a numeric results in a new variable :param other: :return: a new Generic Variable

`__radd__(self, other)`

Take priority on symmetric arithmetic operation :param other: :return:

`__sub__(self, other)`

Subtracting either two variables together or a variable and a numeric results in a new variable :param other:
:return: a new Generic Variable

`__rsub__(self, other)`

Take priority on symmetric arithmetic operation :param other: :return:

`__mul__(self, other)`

Multiplying either two variables together or a variable and a numeric results in a new variable :param other:
:return: a new Generic Variable

`__rmul__(self, other)`

Take priority on symmetric arithmetic operation :param other: :return:

`__truediv__(self, other)`

Dividing either two variables together or a variable and a numeric results in a new variable :param other:
:return: a new Generic Variable

`__rtruediv__(self, other)`

Take priority on symmetric arithmetic operation :param other: :return:

`make_result(self, new_variable)`

Returns a Sympy expression :param new_variable: :return:

`__repr__(self)`

Return repr(self).

`pytfa.optim.get_binary_type()`

FIX : We enforce type to be integer instead of binary, else optlang does not allow to set the binary variable bounds to anything other than (0,1) You might want to set it at (0,0) to enforce directionality for example

pytfa.optim.relax_dgo_gurobi(*model*, *relax_obj_type=0*)

pytfa.optim.relax_dgo(*tmodel*, *reactions_to_ignore=()*, *solver=None*, *in_place=False*)

Parameters

- **t_tmodel** (*pytfa.thermo.ThermoModel*;) –
- **reactions_to_ignore** – Iterable of reactions that should not be relaxed
- **solver** – solver to use (e.g. ‘optlang-glpk’, ‘optlang-cplex’, ‘optlang-gurobi’)

Returns

a cobra_model with relaxed bounds on standard Gibbs free energy

pytfa.optim.**relax_lc**(*tmodel*, *metabolites_to_ignore*=(), *solver*=None)

Parameters

- **metabolites_to_ignore** –
- **in_tmodel** (*pytfa.thermo.ThermoModel*:) –
- **min_objective_value** –

Returns

class pytfa.optim.**GenericConstraint**(*expr*, *id_*="", *model*=None, *hook*=None, *queue*=False, ***kwargs*)

Class to represent a generic constraint. The purpose is that the interface

is instantiated on initialization, to follow the type of interface used by the problem, and avoid incompatibilities in optlang

Attributes:

id

Used for DictList comprehension. Usually points back at a

enzyme or reaction id for ease of linking. Should be unique given a constraint type. **:name:** Should be a concatenation of the id and a prefix that is specific to the variable type. will be used to address the constraint at the solver level, and hence should be unique in the whole cobra_model **:expr:** the expression of the constraint (sympy.Expression subtype) **:cobra_model:** the cobra_model hook. **:constraint:** links directly to the cobra_model representation of the constraint

prefix

property **__attrname__**(*self*)

Name the attribute the instances will have Example: GenericConstraint -> generic_constraint :return:

get_interface(*self*, *expr*, *queue*)

Called upon completion of **__init__**, initializes the value of self.var, which is returned upon call, and stores the actual interfaced variable.

Returns

instance of Variable from the problem

make_name(*self*)

Needs to be overridden by the subclass, concatenates the id with a prefix

Returns

None

change_expr(*self*, *new_expr*, *sloppy*=False)

property **expr**(*self*)

property **name**(*self*)

property **id**(*self*)

for cobra.thermo.DictList compatibility :return:

property constraint(*self*)

property model(*self*)

__repr__(*self*)

Return repr(self).

class pytfa.optim.**ForwardUseVariable**(*reaction*, ****kwargs**)

Bases: [ReactionVariable](#), [BinaryVariable](#)

Class to represent a forward use variable, a type of binary variable used to enforce forward directionality in reaction net fluxes

prefix = FU_

class pytfa.optim.**GenericVariable**(*id_=""*, *model=None*, *hook=None*, *queue=False*, *scaling_factor=1*, ****kwargs**)

Class to represent a generic variable. The purpose is that the interface is instantiated on initialization, to follow the type of interface used by the problem, and avoid incompatibilities in optlang

Attributes:

id

Used for DictList comprehension. Usually points back at a

enzyme or reaction id for ease of linking. Should be unique given a variable type. :name: Should be a concatenation of the id and a prefix that is specific to the variable type. will be used to address the variable at the solver level, and hence should be unique in the whole cobra_model :cobra_model: the cobra_model hook. :variable: links directly to the cobra_model representation of the variable

prefix

property **__attrname__**(*self*)

Name the attribute the instances will have Example: GenericVariable -> generic_variable :return:

get_interface(*self*, *queue*)

Called upon completion of `__init__`, initializes the value of `self.var`, which is returned upon call, and stores the actual interfaced variable.

Returns

instance of Variable from the problem

make_name(*self*)

Needs to be overridden by the subclass, concatenates the id with a prefix

Returns

None

property **name**(*self*)

property `id(self)`

for cobra.thermo.DictList compatibility :return:

property `variable(self)`

property `scaling_factor(self)`

property `unscaled(self)`

If the scaling factor of quantity X is a, it is represented by the variable $X_{\text{hat}} = X/a$. This returns $X = a.X_{\text{hat}}$ Useful for nondimensionalisation of variables and constraints

Returns

The variable divided by its scaling factor

property `value(self)`

property `unscaled_value(self)`

property `model(self)`

property `type(self)`

test_consistency(self, other)

Tests whether a candidate to an operation is of the right type and is from the same problem

Parameters

other – an object

Returns

None

get_operand(self, other)

For operations, choose if the operand is a GenericVariable, in which we return its optlang variable, or something else (presumably a numeric) and we let optlang decide what to do

Parameters

other –

Returns

__add__(self, other)

Adding either two variables together or a variable and a numeric results in a new variable :param other:
:return: a new Generic Variable

__radd__(self, other)

Take priority on symmetric arithmetic operation :param other: :return:

__sub__(self, other)

Subtracting either two variables together or a variable and a numeric results in a new variable :param other:
:return: a new Generic Variable

__rsub__(self, other)

Take priority on symmetric arithmetic operation :param other: :return:

__mul__(self, other)

Multiplying either two variables together or a variable and a numeric results in a new variable :param other:
:return: a new Generic Variable

__rmul__(self, other)

Take priority on symmetric arithmetic operation :param other: :return:

`__truediv__(self, other)`

Dividing either two variables together or a variable and a numeric results in a new variable :param other:
:return: a new Generic Variable

`__rtruediv__(self, other)`

Take priority on symmetric arithmetic operation :param other: :return:

`make_result(self, new_variable)`

Returns a Sympy expression :param new_variable: :return:

`__repr__(self)`

Return repr(self).

`pytfa.optim.SYMPY_ADD_CHUNKSIZE = 100`

`pytfa.optim.INTEGER_VARIABLE_TYPES = ['binary', 'integer']`

`pytfa.optim.get_all_subclasses(cls)`

Given a variable or constraint class, get all the subclasses that inherit from it

Parameters

`cls` –

Returns

`pytfa.optim.chunk_sum(variables)`

This functions handles the sum of many sympy variables by chunks, which somehow increases the speed of the computation

You can test it in IPython: `python a = sympy.symbols('a0:100') %timeit (sum(a)) # >>> 198 µs ± 11.4 µs per loop (mean ± std. dev. of 7 runs, 1 loop each)`

`b = sympy.symbols('b0:1000') %timeit (sum(b)) # >>> 1.85 ms ± 356 µs per loop (mean ± std. dev. of 7 runs, 1 loop each)`

`c = sympy.symbols('c0:3000') %timeit (sum(c)) # >>> 5min 7s ± 2.57 s per loop (mean ± std. dev. of 7 runs, 1 loop each) python`

See the [github thread](#)

Parameters

`variables` –

Returns

`pytfa.optim.symbol_sum(variables)`

`python a = symbols('a0:100')`

`%timeit Add(*a) # >>> 10000 loops, best of 3: 34.1 µs per loop`

`b = symbols('b0:1000')`

`%timeit Add(*b) # >>> 1000 loops, best of 3: 343 µs per loop`

`c = symbols('c0:3000')`

`%timeit Add(*c) # >>> 1 loops, best of 3: 1.03 ms per loop python`

See the [github thread](#) :param variables: :return:

`pytfa.optim.get_solution_value_for_variables(solution, these_vars, index_by_reaction=False)`

`pytfa.optim.compare_solutions(models)`

returns the solution dictionary for each cobra_model :param (iterable (pytfa.thermo.ThermoModel)) models:
:return:

`pytfa.optim.evaluate_constraint_at_solution(constraint, solution)`

Parameters

- **expression** –
- **solution** – pandas.DataFrame, with index as variable names

Returns

`pytfa.optim.get_active_use_variables(tmodel, solution)`

Returns the active use variables in a solution. Use Variables are binary variables that control the directionality of the reaction

ex: FU_ACALDt BU_PFK

Parameters

- **tmodel** (pytfa.core.ThermoModel) –
- **solution** –

Returns

`pytfa.optim.get_direction_use_variables(tmodel, solution)`

Returns the active use variables in a solution. Use Variables are binary variables that control the directionality of the reaction The difference with `get_active_use_variables` is that variables with both UseVariables at 0 will return as going forwards. This is to ensure that the output size of the function is equal to the number of FDPs

ex: FU_ACALDt BU_PFK

Parameters

- **tmodel** (pytfa.core.ThermoModel) –
- **solution** –

Returns

`pytfa.optim.get_primal(tmodel, vartype, index_by_reactions=False)`

Returns the primal value of the cobra_model for variables of a given type :param tmodel: :param vartype: Class of variable. Ex: `pytfa.optim.variables.ThermoDisplacement` :param index_by_reactions: Set to true to get reaction names as index instead of

variables. Useful for Escher export

Returns

`pytfa.optim.strip_from_integer_variables(tmodel)`

Removes all integer and binary variables of a cobra_model, to make it sample-able :param tmodel: :return:

`pytfa.optim.copy_solver_configuration(source, target)`

Copies the solver configuration from a source model to a target model :param source: :param target: :return:

`Lump`

`pytfa.redgem.lumpgem.CPLEX = optlang-cplex`

`pytfa.redgem.lumpgem.GUROBI = optlang-gurobi`

`pytfa.redgem.lumpgem.GLPK = optlang-glpk`

`pytfa.redgem.lumpgem.DEFAULT_EPS = 1e-05`

`pytfa.redgem.lumpgem.disambiguate`

`pytfa.redgem.lumpgem.Lump`

exception `pytfa.redgem.lumpgem.InfeasibleExcept(status, feasibility)`

Bases: `Exception`

Common base class for all non-exit exceptions.

exception `pytfa.redgem.lumpgem.TimeoutExcept(time_limit)`

Bases: `Exception`

Common base class for all non-exit exceptions.

class `pytfa.redgem.lumpgem.FluxKO(reaction, **kwargs)`

Bases: `pytfa.optim.variables.ReactionVariable`, `pytfa.optim.variables.BinaryVariable`

Class to represent a variable attached to a reaction

prefix = `KO_`

class `pytfa.redgem.lumpgem.UseOrKOInt(reaction, expr, **kwargs)`

Bases: `pytfa.optim.constraints.ReactionConstraint`

Class to represent a variable attached to a reaction

prefix = UKI_

class pytfa.redgem.lumpgem.**UseOrKOFlux**(*reaction, expr, **kwargs*)

Bases: pytfa.optim.constraints.ReactionConstraint

Class to represent a variable attached to a reaction

prefix = UKF_

class pytfa.redgem.lumpgem.**LumpGEM**(*tfa_model, additional_core_reactions, params*)

A class encapsulating the LumpGEM algorithm

init_params(*self*)

_generate_usage_constraints(*self*)

Generate carbon intake related constraints for each non-core reaction For each reaction rxn :
rxn.forward_variable + rxn.reverse_variable + activation_var * C_uptake < C_uptake

get_cofactor_adjusted_stoich(*self, rxn*)

_prepare_sinks(*self*)

For each BBB (reactant of the biomass reactions), generate a sink, i.e an unbalanced reaction BBB -> of which purpose is to enable the BBB to be output of the GEM :return: the dict {BBB: sink} containing every BBB (keys) and their associated sinks

_generate_objective(*self*)

Generate and add the maximization objective : set as many activation variables as possible to 1 When an activation variable is set to 1, the corresponding non-core reaction is deactivated

compute_lumps(*self, force_solve=False, method='OnePerBBB'*)

For each BBB (reactant of the biomass reaction), add the corresponding sink to the model, then optimize and lump the result into one lumped reaction :param force_solve: Indicates whether the computations must continue when one lumping yields a status "infeasible" :return: The dict {BBB: lump} containing every lumped reactions, associated to their BBBs

_lump_one_per_bbb(*self, met_BBB, sink, force_solve*)

Parameters

- **met_BBB** –
- **sink** –
- **force_solve** –

Returns

_lump_min_plus_p(*self, met_BBB, sink, p, force_solve*)

Parameters

- **met_BBB** –
- **sink** –
- **force_solve** –

Returns

`_build_lump(self, met_BBB, sink)`

This function uses the current solution of `self._tfa_model`

Parameters

- `met_BBB` –
- `sink` –

Returns

`pytfa.redgem.lumpgem.sum_reactions(rxn_dict, id_='summed_reaction', epsilon=1e-09)`

Keys are reactions Values are their multiplicative coefficient

`pytfa.redgem.network_expansion`

Model class

Module Contents

Classes

NetworkExpansion

class `redgem.NetworkExpansion(gem, core_subsystems, extracellular_system, cofactors, small_metabolites, inorganics, d, n)`

extract_subsystem_reactions(*self, subsystem*)

Extracts all reactions of a subsystem and stores them and their id in the corresponding dictionary.

Parameters

subsystem – Name of the subsystem

Returns

Extracted reactions

extract_subsystem_metabolites(*self, subsystem*)

Extracts all metabolites of a subsystem and stores them and their id in the corresponding dictionary.

Parameters

subsystem – Name of the subsystem

Returns

Extracted metabolites

create_new_stoichiometric_matrix(*self*)

Extracts the new graph without the small metabolites, inorganics and cofactor pairs.

Returns

Networkx graph of the new network

breadth_search_subsystems_paths_length_d(*self, subsystem_i, subsystem_j, d*)

Breadth first search from each metabolite in subsystem i with special stop conditions during exploration for paths of length d.

This function explores the graph through allowed paths only : this path can't go through subsystem i or j but must start in i and end in j. The length of each path found is d.

Parameters

- **subsystem_i** – Source subsystem
- **subsystem_j** – Destination subsystem
- **d** – Path length desired

Returns

None

is_node_allowed(*self, node, i, explored, subsystem_i, subsystem_j, d*)

Checks whether or not a metabolite is allowed for the current path.

The new node is added if it is not already explored, if it is not in the source subsystem, and if it is not in the destination subsystem, except if it is the last round of exploration

Parameters

- **node** – Metabolite id
- **i** – Current step
- **explored** – Explored node for this path
- **subsystem_i** – Source subsystem
- **subsystem_j** – Destination subsystem
- **d** – Path length desired

Returns

Boolean answering the question

retrieve_all_paths(*self, dest_node, src_node, ancestors, init_dict=True*)

Retrieves all paths between a source metabolite and a destination metabolite after a breadth first search.

This function is a recursive function, which makes use of dynamic programming to reduce its complexity. It uses self._path_dict to store already computed data.

Parameters

- **dest_node** – Destination metabolite
- **src_node** – Source metabolite
- **ancestors** – Dictionary with ancestors found during the search
- **init_dict** – Boolean, for function initialisation

Returns

A list of all paths as tuples

retrieve_intermediate_metabolites_and_reactions(*self, paths, subsystem_i, subsystem_j, d*)

Retrieves and stores intermediate metabolites and reactions (i.e. $M_{\{i,j\}}$, $R_{\{i,j\}}$, $M_{\{i,i\}}$ and $R_{\{i,i\}}$).

This function adds all reactions contained in these paths, and all metabolites between

Parameters

- **paths** – List of paths between subsystems
- **subsystem_i** – Source subsystem
- **subsystem_j** – Destination subsystem
- **d** – Path length

Returns

None

find_min_distance_between_subsystems(*self*)

Find minimal distance between each subsystems in both directions

Returns

Dict with distances

breadth_search_extracellular_system_paths(*self, subsystem, n*)

Breadth first search from each metabolite in the extracellular system with special stop conditions during exploration for paths of length *n*.

This function explores the graph through allowed paths only : this path can't go through the extracellular system or the subsystem but must start in the extracellular system and end in the subsystem. The length of each path found is *n*.

Parameters

- **subsystem** – Destination subsystem
- **n** – Path length desired

Returns

None

is_node_allowed_extracellular(*self, node, i, explored, subsystem, n*)

Checks whether or not a metabolite is allowed for the current path.

The new node is added if it is not already explored, if it is not in the extracellular system, and if it is not in the destination subsystem except if it is the last round of exploration

Parameters

- **node** – Metabolite id
- **i** – Current step
- **explored** – Explored node for this path
- **subsystem** – Destination subsystem
- **n** – Path length desired

Returns

Boolean answering the question

retrieve_intermediate_extracellular_metabolites_and_reactions(*self, paths, subsystem, n*)

Retrieves and stores intermediate metabolites and reactions for the extracellular system

This function adds all reactions contained in these paths, and all metabolites between

Parameters

- **paths** – List of paths
- **subsystem** – Destination subsystem

- **n** – Path length

Returns

None

run_between_all_subsystems(*self*)

Retrieve subsystem and intermediate reactions and metabolites.

Returns

None

run_extracellular_system(*self*)

Retrieve intermediate reactions and metabolites for the extracellular system

Returns

None

extract_sub_network(*self*)

Extracts the reduced gem.

Returns

None

run(*self*)

Runs RedGEM.

Returns

None

pytfa.redgem.redgem

Model class

Module Contents**Classes**

 RedGEM

Functions

 add_lump(model, lump_object, id_suffix="")

```
class redgem.RedGEM(gem, parameters_path, inplace=False)
```

```
    read_parameters(self, parameters_path)
```

```
    fill_default_params(self)
```

```
    set_solver(self)
```

`run(self)`

`_extract_inorganics(self)`

Extract inorganics from self._gem based on their formula

Returns

list of inorganics metabolites

`redgem.add_lump(model, lump_object, id_suffix='')`

`pytfa.redgem.utils`

Module Contents

Functions

`remove_blocked_reactions(model)`

`trim_epsilon_mets(met_dict, epsilon)`

`set_medium(model, medium_dict, inplace)`

`pytfa.redgem.utils.remove_blocked_reactions(model)`

`pytfa.redgem.utils.trim_epsilon_mets(met_dict, epsilon)`

`pytfa.redgem.utils.set_medium(model, medium_dict, inplace)`

`pytfa.thermo`

Thermodynamic analysis for Flux-Based Analysis

Submodules

`pytfa.thermo.equilibrator`

Thermodynamic information for metabolites from eQuilibrator.

Module Contents

Functions

<code>build_thermo_from_equilibrator(model, T=TEMPERATURE_0)</code>	Build <i>thermo_data</i> structure from a cobra Model.
---	--

<code>compute_dGf(compound, cc)</code>	Get Gf from equilibrator <i>compound</i> .
--	--

<code>compound_to_entry(compound, cc)</code>	Build thermo structure entry from a <i>equilibrator_cache.Compound</i> .
--	--

Attributes

ccache

logger

pytfa.ccache

pytfa.logger

pytfa.**build_thermo_from_equilibrator**(*model*, *T=TEMPERATURE_0*)

Build *thermo_data* structure from a cobra Model.

The structure of the returned dictionary is specified in the pyTFA [documentation](<https://pytfa.readthedocs.io/en/latest/thermoDB.html>).

Parameters

model – cobra.Model

Return thermo_data

dict to be passed as argument to initialize a *ThermoModel*.

pytfa.**compute_dGf**(*compound*, *cc*)

Get Gf from equilibrator *compound*.

pytfa.**compound_to_entry**(*compound*, *cc*)

Build thermo structure entry from a *equilibrator_cache.Compound*.

eQuilibrator works with Component Contribution instead of groups, so it is not possible to generate cues from it.

Parameters

compound – equilibrator_cache.Compound

Returns

dict with keys ['deltaGf_std', 'deltaGf_err', 'error', 'struct_cues', 'id', 'pKa', 'mass_std', 'charge_std', 'nH_std', 'name', 'formula', 'other_names']

pytfa.thermo.metabolite

Thermodynamic computations for metabolites

Module Contents

Classes

MetaboliteThermo

A class representing the thermodynamic values of a enzyme

Attributes

CPD_PROTON

DEFAULT_VAL

pytfa.CPD_PROTON = cpd00067

pytfa.DEFAULT_VAL

```
class pytfa.MetaboliteThermo(metData, pH, ionicStr, temperature=std.TEMPERATURE_0,
                             min_ph=std.MIN_PH, max_ph=std.MAX_PH,
                             debye_huckel_b=std.DEBYE_HUCKEL_B_0, thermo_unit='kJ/mol',
                             debug=False)
```

A class representing the thermodynamic values of a enzyme

Parameters

- **metData** (*dict*) – A dictionary containing the values for the enzyme, from the thermodynamic database
- **pH** (*float*) – The pH of the enzyme’s compartment
- **ionicStr** (*float*) – The ionic strength of the enzyme’s compartment
- **temperature** –
- **min_ph** –
- **max_ph** –
- **debye_huckel_b** –
- **thermo_unit** (*string*) – The unit used in *metData*’s values
- **debug** (*bool*) – *Optional* If set to True, some debugging values will be printed. This is only useful for development or debugging purposes.

Note: The values are automatically computed on class creation. Usually you don’t have to call any methods defined by this class, but only to access the attributes you need.

The available attributes are :

Since the reactions expose similar values through a dictionary, it is better to access the attributes aforementioned of this class as if it was a dictionary : `enzyme.thermo['pH']`.

`__getitem__(self, key)`

`__repr__(self)`

Return repr(self).

`keys(self)`

`values(self)`

`items(self)`

`__cmp__(self, dict_)`

`__contains__(self, item)`

`__iter__(self)`

`__unicode__(self)`

`calcDGis(self)`

Calculate the transformed Gibbs energy of formation of specie with given pH and ionic strength using formula given by Goldberg and Tewari, 1991

Equation 4.5-6 in Alberty's book

Returns

DG_is for the enzyme

Return type

float

`calcDGsp(self)`

Calculate the transformed Gibbs energy of formation of specie with given pH and ionic strength using formula given by Goldberg and Tewari, 1991

Equation 4.4-10 in Alberty's book

Returns

DG_sp for the enzyme

Return type

float

`calc_potential(self)`

Calculate the binding polynomial of a specie, with pK values

Returns

The potential of the enzyme

Return type

float

`get_pka(self)`

Get the pKas of the enzyme

Returns

The pKas of the enzyme

Return type

list(float)

`_calc_pka(self, pka, sigmanusq)`

`calcDGspA(self)`

Calculates deltaGf, charge and nH of the specie when it is at least protonated state based on MFAToolkit compound data for the pKa values within the range considered (MIN_pH to MAX_pH).

These values are used as the starting point for Alberty's calculations.

Returns

deltaGspA, sp_charge and sp_nH

Return type

tuple(float, float, int)

pytfa.thermo.reaction

Thermodynamic computations for reactions

Module Contents

Functions

<code>calcDGtpt_rhs(reaction, thermo_units)</code>	<code>compartmentsData,</code>	Calculates the RHS of the deltaG constraint, i.e. the sum of the
<code>calcDGR_cues(reaction, reaction_cues_data)</code>		Calculates the deltaG reaction and error of the reaction using the
<code>calcDGF_cues(cues, reaction_cues_data)</code>		Calculates the deltaG formation and error of the compound using its
<code>get_debye_huckel_b(T)</code>		The Debye-Huckel A and B do depend on the temperature

`pytfa.calcDGtpt_rhs(reaction, compartmentsData, thermo_units)`

Calculates the RHS of the deltaG constraint, i.e. the sum of the non-concentration terms

Parameters

- **reaction** (`cobra.thermo.reaction.Reaction`) – The reaction to compute the data for
- **compartmentsData** (`dict(float)`) – Data of the compartments of the cobra_model
- **thermo_units** (`str`) – The thermodynamic database of the cobra_model

Returns

deltaG_tpt and the breakdown of deltaG_tpt

Return type

`tuple(float, dict(float))`

Example:

ATP Synthase reaction:

```
reaction = cpd00008 + 4 cpd00067 + cpd00009 <=> cpd00002 + 3 cpd00067 + cpd00001
compartments = 'c' 'e' 'c' 'c' 'c' 'c'
```

If there are any metabolites with unknown energies then returns

`(0, None)`.

`pytfa.calcDGR_cues(reaction, reaction_cues_data)`

Calculates the deltaG reaction and error of the reaction using the constituent structural cues changes and returns also the error if any.

Parameters

- **reaction** (`cobra.thermo.reaction.Reaction`) – The reaction to compute deltaG for
- **reaction_cues_data** (`dict`) –

Returns

deltaGR, error on deltaGR, the cues in the reaction (keys of the dictionary) and their indices (values of the dictionary), and the error code if any.

If everything went right, the error code is an empty string

Return type

`tuple(float, float, dict(float), str)`

`pytfa.calcDGF_cues(cues, reaction_cues_data)`

Calculates the deltaG formation and error of the compound using its constituent structural cues.

Parameters

- **cues** (*list(str)*) – A list of cues' names
- **reaction_cues_data** (*dict*) –

Returns

deltaG formation, the error on deltaG formation, and a dictionary with the cues' names as key and their coefficient as value

Return type

`tuple(float, float, dict(float)).`

`pytfa.get_debye_huckel_b(T)`

The Debye-Huckel A and B do depend on the temperature As for now though they are returned as a constant (value at 298.15K)

Parameters

T – Temperature in Kelvin

Returns

Debye_Huckel_B

pytfa.thermo.std

Standard constants definitions

Module Contents

`pytfa.thermo.std.TEMPERATURE_0 = 298.15`

`pytfa.thermo.std.MIN_PH = 3`

`pytfa.thermo.std.MAX_PH = 9`

`pytfa.thermo.std.DEBYE_HUCKEL_B_0 = 1.6`

`pytfa.thermo.std.DEBYE_HUCKEL_A`

`pytfa.thermo.std.A_LOT = 5000`

`pytfa.thermo.std.A_LITTLE = 0.5`

`pytfa.thermo.std.A_COUPLE = 2.5`

`pytfa.thermo.std.MANY = 100`

pytfa.thermo.tmodel

Thermodynamic cobra_model class and methods definition

Module Contents

Classes

ThermoModel	A class representing a cobra_model with thermodynamics information
-------------	--

Attributes

BIGM
BIGM_THERMO
BIGM_DG
BIGM_P
EPSILON
MAX_STOICH

pytfa.BIGM

pytfa.BIGM_THERMO

pytfa.BIGM_DG

pytfa.BIGM_P

pytfa.EPSILON

pytfa.MAX_STOICH = 10

```
class pytfa.ThermoModel(thermo_data=None, model=Model(), name=None,
                        temperature=std.TEMPERATURE_0, min_ph=std.MIN_PH, max_ph=std.MAX_PH)
```

Bases: pytfa.core.model.LCSBModel, cobra.Model

A class representing a cobra_model with thermodynamics information

`_init_thermo(self)`

`normalize_reactions(self)`

Find reactions with important stoichiometry and normalizes them :return:

`_prepare_metabolite(self, met)`

Parameters

met –

Returns

`_prepare_reaction(self, reaction, null_error_override=2)`

Parameters

- **reaction** –
- **null_error_override** – overrides DeltaG when it is 0 to allow flexibility. 2kcal/mol is standard in estimation frameworks like GCM.

Returns

`prepare(self, null_error_override=2)`

Prepares a COBRA toolbox cobra_model for TFBA analysis by doing the following:

1. checks if a reaction is a transport reaction
2. checks the ReactionDB for Gibbs energies of formation of metabolites
3. computes the Gibbs energies of reactions

Parameters

null_error_override – overrides DeltaG when it is 0 to allow flexibility. 2kcal/mol is standard in estimation frameworks like GCM.

`_convert_metabolite(self, met, add_potentials, verbose)`

Given a enzyme, proceeds to create the necessary variables and constraints for thermodynamics-based modeling

Parameters

met –

Returns

`_convert_reaction(self, rxn, add_potentials, add_displacement, verbose)`

Parameters

- **rxn** –
- **add_potentials** –
- **add_displacement** –
- **verbose** –

Returns

`convert(self, add_potentials=False, add_displacement=False, verbose=True)`

Converts a cobra_model into a tFBA ready cobra_model by adding the thermodynamic constraints required

Warning: This function requires you to have already called `prepare()`, otherwise it will raise an Exception !

`print_info(self, specific=False)`

Print information and counts for the cobra_model :return:

`__deepcopy__(self, memo)`

Parameters

memo –

Returns

`copy(self)`

Needs to be reimplemented, as our objects have complicated hierarchy :return:

pytfa.thermo.utils

Some tools around COBRApy models used by pyTFA

Module Contents

Functions

<code>check_reaction_balance(reaction, proton=None)</code>	Check the balance of a reaction, and eventually add protons to balance
<code>find_transported_mets(reaction)</code>	Get a list of the transported metabolites of the reaction.
<code>check_transport_reaction(reaction)</code>	Check if a reaction is a transport reaction
<code>is_same_stoichiometry(this_reaction, that_reaction)</code>	
<code>is_exchange(rxn)</code>	
<code>get_reaction_compartment(reaction)</code>	Get the compartment of a reaction to then prepare it for conversion.

Attributes

<code>Formula_regex</code>

pytfa.Formula_regex

`pytfa.check_reaction_balance(reaction, proton=None)`

Check the balance of a reaction, and eventually add protons to balance it

Parameters

- **reaction** (*cobra.thermo.reaction.Reaction*) – The reaction to check the balance of.
- **proton** (*cobra.thermo.metabolite.Metabolite*) – *Optional* The proton to add to the reaction to balance it.

Returns

The balance of the reaction :

- drain flux
- missing structures
- balanced
- N protons added to reactants with N a `float`
- N protons added to products with N a `float`
- missing atoms

Return type`str`

If `proton` is provided, this function will try to balance the equation with it, and return the result.

If no `proton` is provided, this function will not try to balance the equation.

Warning: This function does not verify if `proton` is in the correct compartment, so make sure you provide the `proton` belonging to the correct compartment !

`pytfa.find_transported_mets(reaction)`

Get a list of the transported metabolites of the reaction.

Parameters

reaction (`cobra.thermo.reaction.Reaction`) – The reaction to get the transported metabolites of

Returns

A dictionary of the transported metabolites. The index corresponds to the `seed_id` of the transported enzyme

The value is a dictionary with the following values:

- **coeff (float):**
The stoichiometric coefficient of the enzyme
- **reactant (cobra.thermo.enzyme.Metabolite):**
The reactant of the reaction corresponding to the transported enzyme
- **product (cobra.thermo.enzyme.Metabolite):**
The product of the reaction corresponding to the transported enzyme

A transported enzyme is defined as a enzyme which is a product and a reactant of a reaction. We can distinguish them thanks to their `seed_ids`.

`pytfa.check_transport_reaction(reaction)`

Check if a reaction is a transport reaction

Parameters

reaction (`cobra.thermo.reaction.Reaction`) – The reaction to check

Returns

Whether the reaction is a transport reaction or not

Return type`bool`

A transport reaction is defined as a reaction that has the same compound as a reactant and a product. We can distinguish them thanks to their `seed_ids`. If they have one If not, use `met_ids` and check if they are the same, minus compartment

`pytfa.is_same_stoichiometry(this_reaction, that_reaction)`

`pytfa.is_exchange(rxn)`

`pytfa.get_reaction_compartment(reaction)`

Get the compartment of a reaction to then prepare it for conversion.

Package Contents

Classes

<i>MetaboliteThermo</i>	A class representing the thermodynamic values of a enzyme
<i>SimultaneousUse</i>	Class to represent a simultaneous use constraint on reaction variables
<i>NegativeDeltaG</i>	Class to represent thermodynamics constraints.
<i>BackwardDeltaGCoupling</i>	Class to represent thermodynamics coupling: DeltaG of reactions has to be
<i>ForwardDeltaGCoupling</i>	Class to represent thermodynamics coupling: DeltaG of reactions has to be
<i>BackwardDirectionCoupling</i>	Class to represent a backward directionality coupling with thermodynamics on
<i>ForwardDirectionCoupling</i>	Class to represent a forward directionality coupling with thermodynamics on
<i>ReactionConstraint</i>	Class to represent a variable attached to a reaction
<i>MetaboliteConstraint</i>	Class to represent a variable attached to a enzyme
<i>DisplacementCoupling</i>	Class to represent the coupling to the thermodynamic displacement
<i>ThermoDisplacement</i>	Class to represent the thermodynamic displacement of a reaction
<i>DeltaGstd</i>	Class to represent a ΔG° (naught) - standard conditions
<i>DeltaG</i>	Class to represent a ΔG
<i>ForwardUseVariable</i>	Class to represent a forward use variable, a type of binary variable used to
<i>BackwardUseVariable</i>	Class to represent a backward use variable, a type of binary variable used
<i>LogConcentration</i>	Class to represent a log concentration of a enzyme
<i>ReactionVariable</i>	Class to represent a variable attached to a reaction
<i>MetaboliteVariable</i>	Class to represent a variable attached to a enzyme
<i>ThermoModel</i>	A class representing a cobra_model with thermodynamics information
<i>MetaboliteThermo</i>	A class representing the thermodynamic values of a enzyme

Functions

<code>calcDGtpt_rhs</code> (reaction, thermo_units)	compartmentsData,	Calculates the RHS of the deltaG constraint, i.e. the sum of the

<code>find_transporteds_mets</code> (reaction)		Get a list of the transported metabolites of the reaction.
<code>get_reaction_compartment</code> (reaction)		Get the compartment of a reaction to then prepare it for conversion.
<code>get_bistream_logger</code> (name)		Sets up a logger that outputs INFO+ messages on stdout and DEBUG+ messages

Attributes

`BIGM`

`BIGM_THERMO`

`BIGM_DG`

`BIGM_P`

`EPSILON`

`MAX_STOICH`

```
class pytfa.thermo.MetaboliteThermo(metData, pH, ionicStr, temperature=std.TEMPERATURE_0,
                                     min_ph=std.MIN_PH, max_ph=std.MAX_PH,
                                     debye_huckel_b=std.DEBYE_HUCKEL_B_0, thermo_unit='kJ/mol',
                                     debug=False)
```

A class representing the thermodynamic values of a enzyme

Parameters

- **metData** (*dict*) – A dictionary containing the values for the enzyme, from the thermodynamic database
- **pH** (*float*) – The pH of the enzyme’s compartment
- **ionicStr** (*float*) – The ionic strength of the enzyme’s compartment
- **temperature** –
- **min_ph** –
- **max_ph** –
- **debye_huckel_b** –

- **thermo_unit** (*string*) – The unit used in *metData*'s values
- **debug** (*bool*) – *Optional* If set to True, some debugging values will be printed. This is only useful for development or debugging purposes.

Note: The values are automatically computed on class creation. Usually you don't have to call any methods defined by this class, but only to access the attributes you need.

The available attributes are :

Since the reactions expose similar values through a dictionary, it is better to access the attributes aforementioned of this class as if it was a dictionary : `enzyme.thermo['pH']`.

`__getitem__`(*self, key*)

`__repr__`(*self*)

Return repr(self).

`keys`(*self*)

`values`(*self*)

`items`(*self*)

`__cmp__`(*self, dict_*)

`__contains__`(*self, item*)

`__iter__`(*self*)

`__unicode__`(*self*)

`calcDGis`(*self*)

Calculate the transformed Gibbs energy of formation of specie with given pH and ionic strength using formula given by Goldberg and Tewari, 1991

Equation 4.5-6 in Alberty's book

Returns

DG_{is} for the enzyme

Return type

float

`calcDGsp`(*self*)

Calculate the transformed Gibbs energy of formation of specie with given pH and ionic strength using formula given by Goldberg and Tewari, 1991

Equation 4.4-10 in Alberty's book

Returns

DG_{sp} for the enzyme

Return type

float

`calc_potential`(*self*)

Calculate the binding polynomial of a specie, with pK values

Returns

The potential of the enzyme

Return type

float

get_pka(*self*)

Get the pKas of the enzyme

Returns

The pKas of the enzyme

Return type

list(float)

_calc_pka(*self*, *pka*, *sigmanusq*)**calcDGspA**(*self*)

Calculates deltaGf, charge and nH of the specie when it is at least protonated state based on MFAToolkit compound data for the pKa values within the range considered (MIN_pH to MAX_pH).

These values are used as the starting point for Alberty's calculations.

Returns

deltaGspA, sp_charge and sp_nH

Return type

tuple(float, float, int)

pytfa.thermo.calcDGtpt_rhs(*reaction*, *compartmentsData*, *thermo_units*)

Calculates the RHS of the deltaG constraint, i.e. the sum of the non-concentration terms

Parameters

- **reaction** (*cobra.thermo.reaction.Reaction*) – The reaction to compute the data for
- **compartmentsData** (*dict(float)*) – Data of the compartments of the cobra_model
- **thermo_units** (*str*) – The thermodynamic database of the cobra_model

Returns

deltaG_tpt and the breakdown of deltaG_tpt

Return type

tuple(float, dict(float))

Example:

ATP Synthase reaction:

```
reaction = cpd000008 + 4 cpd000067 + cpd000009 <=> cpd000002 + 3 cpd000067 + cpd000001
compartments = 'c'      'e'      'c'      'c'      'c'      'c'      'c'
```

If there are any metabolites with unknown energies then returns

(0, None).

pytfa.thermo.calcDGR_cues(*reaction*, *reaction_cues_data*)

Calculates the deltaG reaction and error of the reaction using the constituent structural cues changes and returns also the error if any.

Parameters

- **reaction** (*cobra.thermo.reaction.Reaction*) – The reaction to compute deltaG for
- **reaction_cues_data** (*dict*) –

Returns

deltaGR, error on deltaGR, the cues in the reaction (keys of the dictionary) and their indices (values of the dictionary), and the error code if any.

If everything went right, the error code is an empty string

Return type

`tuple(float, float, dict(float), str)`

`pytfa.thermo.get_debye_huckel_b(T)`

The Debye-Huckel A and B do depend on the temperature As for now though they are returned as a constant (value at 298.15K)

Parameters

T – Temperature in Kelvin

Returns

Debye_Huckel_B

`pytfa.thermo.check_reaction_balance(reaction, proton=None)`

Check the balance of a reaction, and eventually add protons to balance it

Parameters

- **reaction** (`cobra.thermo.reaction.Reaction`) – The reaction to check the balance of.
- **proton** (`cobra.thermo.metabolite.Metabolite`) – *Optional* The proton to add to the reaction to balance it.

Returns

The balance of the reaction :

- drain flux
- missing structures
- balanced
- N protons added to reactants with N a `float`
- N protons added to products with N a `float`
- missing atoms

Return type

`str`

If `proton` is provided, this function will try to balance the equation with it, and return the result.

If no `proton` is provided, this function will not try to balance the equation.

Warning: This function does not verify if `proton` is in the correct compartment, so make sure you provide the proton belonging to the correct compartment !

`pytfa.thermo.check_transport_reaction(reaction)`

Check if a reaction is a transport reaction

Parameters

reaction (`cobra.thermo.reaction.Reaction`) – The reaction to check

Returns

Whether the reaction is a transport reaction or not

Return type

`bool`

A transport reaction is defined as a reaction that has the same compound as a reactant and a product. We can distinguish them thanks to their `seed_ids`. If they have one If not, use `met_ids` and check if they are the same, minus compartment

`pytfa.thermo.find_transported_mets(reaction)`

Get a list of the transported metabolites of the reaction.

Parameters

reaction (`cobra.thermo.reaction.Reaction`) – The reaction to get the transported metabolites of

Returns

A dictionary of the transported metabolites. The index corresponds to the `seed_id` of the transported enzyme

The value is a dictionary with the following values:

- **coeff (float):**
The stoichiometric coefficient of the enzyme
- **reactant (cobra.thermo.enzyme.Metabolite):**
The reactant of the reaction corresponding to the transported enzyme
- **product (cobra.thermo.enzyme.Metabolite):**
The product of the reaction corresponding to the transported enzyme

A transported enzyme is defined as a enzyme which is a product and a reactant of a reaction. We can distinguish them thanks to their `seed_ids`.

`pytfa.thermo.get_reaction_compartment(reaction)`

Get the compartment of a reaction to then prepare it for conversion.

class `pytfa.thermo.SimultaneousUse(reaction, expr, **kwargs)`

Bases: `ReactionConstraint`

Class to represent a simultaneous use constraint on reaction variables Looks like: $SU_{rxn} + FU_{rxn} + BU_{rxn} \leq 1$

prefix = `SU_`

class `pytfa.thermo.NegativeDeltaG(reaction, expr, **kwargs)`

Bases: `ReactionConstraint`

Class to represent thermodynamics constraints.

G: $-DGR_{rxn} + DGoRerr_{Rxn} + RT * StoichCoefProd1 * LC_{prod1}$

- $RT * StoichCoefProd2 * LC_{prod2}$
- $RT * StoichCoefSub1 * LC_{subs1}$
- $RT * StoichCoefSub2 * LC_{subs2}$
- ...

= 0

prefix = G_

class pytfa.thermo.**BackwardDeltaGCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent thermodynamics coupling: DeltaG of reactions has to be $DGR > 0$ for the reaction to proceed backwards Looks like: BU_rxn: 1000 BU_rxn - DGR_rxn < 1000

prefix = BU_

class pytfa.thermo.**ForwardDeltaGCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent thermodynamics coupling: DeltaG of reactions has to be $DGR < 0$ for the reaction to proceed forwards Looks like: FU_rxn: 1000 FU_rxn + DGR_rxn < 1000

prefix = FU_

class pytfa.thermo.**BackwardDirectionCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent a backward directionality coupling with thermodynamics on reaction variables Looks like : UR_rxn: R_rxn - M RU_rxn < 0

prefix = UR_

class pytfa.thermo.**ForwardDirectionCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent a forward directionality coupling with thermodynamics on reaction variables Looks like : UF_rxn: F_rxn - M FU_rxn < 0

prefix = UF_

class pytfa.thermo.**ReactionConstraint**(*reaction, expr, **kwargs*)

Bases: *GenericConstraint*

Class to represent a variable attached to a reaction

prefix = RC_

property *reaction*(*self*)

property *id*(*self*)

for cobra.thermo.DictList compatibility :return:

property *model*(*self*)

class pytfa.thermo.**MetaboliteConstraint**(*metabolite, expr, **kwargs*)

Bases: *GenericConstraint*

Class to represent a variable attached to a enzyme

prefix = MC_

property *metabolite*(*self*)

property *id*(*self*)

for cobra.thermo.DictList compatibility :return:

property *model*(*self*)

class pytfa.thermo.**DisplacementCoupling**(*reaction, expr, **kwargs*)

Bases: *ReactionConstraint*

Class to represent the coupling to the thermodynamic displacement Looks like: $\ln(\Gamma) - (1/RT)*DGR_{rxn} = 0$

prefix = DC_

class pytfa.thermo.**ThermoDisplacement**(*reaction, **kwargs*)

Bases: *ReactionVariable*

Class to represent the thermodynamic displacement of a reaction $\Gamma = -\Delta G/RT$

prefix = LnGamma_

class pytfa.thermo.**DeltaGstd**(*reaction, **kwargs*)

Bases: *ReactionVariable*

Class to represent a ΔG^o (naught) - standard conditions

prefix = DGo_

class pytfa.thermo.**DeltaG**(*reaction, **kwargs*)

Bases: *ReactionVariable*

Class to represent a ΔG

prefix = DG_

class pytfa.thermo.**ForwardUseVariable**(*reaction, **kwargs*)

Bases: *ReactionVariable*, *BinaryVariable*

Class to represent a forward use variable, a type of binary variable used to enforce forward directionality in reaction net fluxes

prefix = FU_

class pytfa.thermo.**BackwardUseVariable**(*reaction, **kwargs*)

Bases: *ReactionVariable*, *BinaryVariable*

Class to represent a backward use variable, a type of binary variable used to enforce backward directionality in reaction net fluxes

prefix = BU_

class pytfa.thermo.**LogConcentration**(*metabolite, **kwargs*)

Bases: *MetaboliteVariable*

Class to represent a log concentration of a enzyme

prefix = LC_

class pytfa.thermo.**ReactionVariable**(*reaction, **kwargs*)

Bases: *GenericVariable*

Class to represent a variable attached to a reaction

prefix = RV_

property *reaction*(*self*)

property `id(self)`

for cobra.thermo.DictList compatibility :return:

property `model(self)`

class `pytfa.thermo.MetaboliteVariable(metabolite, **kwargs)`

Bases: `GenericVariable`

Class to represent a variable attached to a enzyme

prefix = `MV_`

property `metabolite(self)`

property `id(self)`

for cobra.thermo.DictList compatibility :return:

property `model(self)`

`pytfa.thermo.get_bistream_logger(name)`

Sets up a logger that outputs INFO+ messages on stdout and DEBUG+ messages in the log file

Parameters

name – a class `__name__` attribute

Returns

`pytfa.thermo.BIGM`

`pytfa.thermo.BIGM_THERMO`

`pytfa.thermo.BIGM_DG`

`pytfa.thermo.BIGM_P`

`pytfa.thermo.EPSILON`

`pytfa.thermo.MAX_STOICH = 10`

class `pytfa.thermo.ThermoModel(thermo_data=None, model=Model(), name=None,
temperature=std.TEMPERATURE_0, min_ph=std.MIN_PH,
max_ph=std.MAX_PH)`

Bases: `pytfa.core.model.LCSBModel`, `cobra.Model`

A class representing a cobra_model with thermodynamics information

`_init_thermo(self)`

`normalize_reactions(self)`

Find reactions with important stoichiometry and normalizes them :return:

`_prepare_metabolite(self, met)`

Parameters

met –

Returns

`_prepare_reaction(self, reaction, null_error_override=2)`

Parameters

- **reaction** –
- **null_error_override** – overrides DeltaG when it is 0 to allow flexibility. 2kcal/mol is standard in estimation frameworks like GCM.

Returns

`prepare(self, null_error_override=2)`

Prepares a COBRA toolbox cobra_model for TFBA analysis by doing the following:

1. checks if a reaction is a transport reaction
2. checks the ReactionDB for Gibbs energies of formation of metabolites
3. computes the Gibbs energies of reactions

Parameters

- **null_error_override** – overrides DeltaG when it is 0 to allow flexibility. 2kcal/mol is standard in estimation frameworks like GCM.

`_convert_metabolite(self, met, add_potentials, verbose)`

Given a enzyme, proceeds to create the necessary variables and constraints for thermodynamics-based modeling

Parameters

- **met** –

Returns

`_convert_reaction(self, rxn, add_potentials, add_displacement, verbose)`

Parameters

- **rxn** –
- **add_potentials** –
- **add_displacement** –
- **verbose** –

Returns

`convert(self, add_potentials=False, add_displacement=False, verbose=True)`

Converts a cobra_model into a tFBA ready cobra_model by adding the thermodynamic constraints required

Warning: This function requires you to have already called `prepare()`, otherwise it will raise an Exception !

`print_info(self, specific=False)`

Print information and counts for the cobra_model :return:

`__deepcopy__(self, memo)`

Parameters

- **memo** –

Returns

`copy(self)`

Needs to be reimplemented, as our objects have complicated hierarchy :return:

```
class pytfa.thermo.MetaboliteThermo(metData, pH, ionicStr, temperature=std.TEMPERATURE_0,
                                   min_ph=std.MIN_PH, max_ph=std.MAX_PH,
                                   debye_huckel_b=std.DEBYE_HUCKEL_B_0, thermo_unit='kJ/mol',
                                   debug=False)
```

A class representing the thermodynamic values of a enzyme

Parameters

- **metData** (*dict*) – A dictionary containing the values for the enzyme, from the thermodynamic database
- **pH** (*float*) – The pH of the enzyme’s compartment
- **ionicStr** (*float*) – The ionic strength of the enzyme’s compartment
- **temperature** –
- **min_ph** –
- **max_ph** –
- **debye_huckel_b** –
- **thermo_unit** (*string*) – The unit used in *metData*’s values
- **debug** (*bool*) – *Optional* If set to True, some debugging values will be printed. This is only useful for development or debugging purposes.

Note: The values are automatically computed on class creation. Usually you don’t have to call any methods defined by this class, but only to access the attributes you need.

The available attributes are :

Since the reactions expose similar values through a dictionary, it is better to access the attributes aforementioned of this class as if it was a dictionary : `enzyme.thermo['pH']`.

`__getitem__(self, key)`

`__repr__(self)`

Return repr(self).

`keys(self)`

`values(self)`

`items(self)`

`__cmp__(self, dict_)`

`__contains__(self, item)`

`__iter__(self)`

`__unicode__(self)`

calcDGis(*self*)

Calculate the transformed Gibbs energy of formation of specie with given pH and ionic strength using formula given by Goldberg and Tewari, 1991

Equation 4.5-6 in Alberty's book

Returns

DG_is for the enzyme

Return type

float

calcDGsp(*self*)

Calculate the transformed Gibbs energy of formation of specie with given pH and ionic strength using formula given by Goldberg and Tewari, 1991

Equation 4.4-10 in Alberty's book

Returns

DG_sp for the enzyme

Return type

float

calc_potential(*self*)

Calculate the binding polynomial of a specie, with pK values

Returns

The potential of the enzyme

Return type

float

get_pka(*self*)

Get the pKas of the enzyme

Returns

The pKas of the enzyme

Return type

list(float)

_calc_pka(*self*, *pka*, *sigmanusq*)**calcDGspA**(*self*)

Calculates deltaGf, charge and nH of the specie when it is at least protonated state based on MFAToolkit compound data for the pKa values within the range considered (MIN_pH to MAX_pH).

These values are used as the starting point for Alberty's calculations.

Returns

deltaGspA, sp_charge and sp_nH

Return type

tuple(float, float, int)

pytfa.utils

Submodules

pytfa.utils.logger

Module Contents

Functions

<code>get_bistream_logger(name)</code>	Sets up a logger that outputs INFO+ messages on stdout and DEBUG+ messages
<code>get_timestr()</code>	

Attributes

`LOGFOLDERNAME`

`pytfa.LOGFOLDERNAME = logs`

`pytfa.get_bistream_logger(name)`

Sets up a logger that outputs INFO+ messages on stdout and DEBUG+ messages in the log file

Parameters

name – a class `__name__` attribute

Returns

`pytfa.get_timestr()`

pytfa.utils.numerics

BIG M and epsilon constants definitions

Module Contents

`pytfa.utils.numerics.BIGM = 1000`

`pytfa.utils.numerics.BIGM_THERMO = 1000.0`

Classes

ThermoModel A class representing a cobra_model with thermodynamics information

class pytfa.**ThermoModel**(thermo_data=None, model=Model(), name=None, temperature=std.TEMPERATURE_0, min_ph=std.MIN_PH, max_ph=std.MAX_PH)

Bases: pytfa.core.model.LCSBModel, cobra.Model

A class representing a cobra_model with thermodynamics information

_init_thermo(self)

normalize_reactions(self)

Find reactions with important stoichiometry and normalizes them :return:

_prepare_metabolite(self, met)

Parameters

met –

Returns

_prepare_reaction(self, reaction, null_error_override=2)

Parameters

- **reaction** –
- **null_error_override** – overrides DeltaG when it is 0 to allow flexibility. 2kcal/mol is standard in estimation frameworks like GCM.

Returns

prepare(*self*, *null_error_override=2*)

Prepares a COBRA toolbox cobra_model for TFBA analysis by doing the following:

1. checks if a reaction is a transport reaction
2. checks the ReactionDB for Gibbs energies of formation of metabolites
3. computes the Gibbs energies of reactions

Parameters

null_error_override – overrides DeltaG when it is 0 to allow flexibility. 2kcal/mol is standard in estimation frameworks like GCM.

_convert_metabolite(*self*, *met*, *add_potentials*, *verbose*)

Given a enzyme, proceeds to create the necessary variables and constraints for thermodynamics-based modeling

Parameters

met –

Returns

_convert_reaction(*self*, *rxn*, *add_potentials*, *add_displacement*, *verbose*)

Parameters

- **rxn** –
- **add_potentials** –
- **add_displacement** –
- **verbose** –

Returns

convert(*self*, *add_potentials=False*, *add_displacement=False*, *verbose=True*)

Converts a cobra_model into a tFBA ready cobra_model by adding the thermodynamic constraints required

Warning: This function requires you to have already called `prepare()`, otherwise it will raise an Exception !

print_info(*self*, *specific=False*)

Print information and counts for the cobra_model :return:

__deepcopy__(*self*, *memo*)

Parameters

memo –

Returns

copy(*self*)

Needs to be reimplemented, as our objects have complicated hierarchy :return:
